SOME PRINCIPLES OF MEDICAL ETHICS APPLIED TO THE PRACTICE OF OPHTHALMOLOGY

CHAIRMAN'S ADDRESS

ALBERT C. SNELL, M.D.
ROCHESTER, N. Y.

Since my election to the chairmanship of this section, I have received considerable correspondence with reference to certain questionable practices of ophthalmologists in the dispensing of ophthalmic lenses. Also there has appeared in a high class nationally distributed magazine a critical and informative article setting forth principally those practices which are no credit to the profession. The time, therefore, seems opportune to examine some common methods of practices and to compare them with the historically established ethical principles of our profession.

The principles of medical ethics are just as binding on those practicing ophthalmology as they are on all other members of the medical profession. There are, however, some situations which are peculiar to the special practice of ophthalmology. These situations present unusual temptations to violate our best ethical standards. It is my purpose in this address to bring anew to your attention some of these principles of ethics and apply them to some common methods of practice in order that these methods may be analyzed. I hope that each individual ophthalmologist will compare his method of practice with that type of ethical conduct which is demanded by the medical profession.

It is much to be desired that both individual ophthalmologists and organized groups will strive to correct any unethical conduct that may be found to prevail. Some forms of practice not only are bringing disrespect and dishonor to the profession but much positive harm as well. When ethical principles and ideals of the medical profession are not respected by even a small group of ophthalmologists, opprobrium is placed on the entire profession, the ethical and the unethical alike. Every individual ophthalmologist becomes the object of derision. This is illustrated by the article mentioned, which sets forth information of certain under-cover, questionable trade practices existing between dispensing opticians and ophthalmologists. For example, the article informs the public that the dispensing optician "may sell direct to the patient, under an arrangement which would shock that patient rudely if he understood it." The article states further that the patient may have

been deluded into thinking that the wholesale price is charged by the dispenser, whereas a full retail price is collected "which he later splits, on the quiet, with your physician." This article also states that "kick-back," "furtive fee-splitting" is not exceptional; that the ophthalmologist pockets a retail price for services *which he does not render*. This practice sometimes is given the softer and more subtle term of a "differential." All these forms of participation in the profits from the supplying of ophthalmic lenses and mountings are usually done without the knowledge of the patient and without rendering any special service to the patient. These are some of the grounds on which ophthalmologists are indicted not only by the public but also by the medical profession. What is your answer to this indictment? Shady and secret methods of rebating which are by no means uncommon can be kept in the dark no longer.

FUNDAMENTAL PRINCIPLES OF ETHICAL CONDUCT

Let me review a few fundamental principles to which all physicians are obligated in order that a foundation may be laid for the proper answer to this indictment and that all may comprehend the approved standard of ethical conduct.

In the booklet¹ published by the American Medical Association the fundamental principle which should activate the relation between the physician and his patients is stated thus:²

A profession has for its prime object the service it can render to humanity; reward or financial gain should be a subordinate consideration.

The question of proper ethical conduct can always be answered by applying this principle. Does the possibility of financial and selfish gain predominate, or do we consider the interest of the patient as most important? I commend the reading of this entire booklet to all ophthalmologists. It briefly and clearly sets forth the ideals which should dominate the physician's conduct and his obligations to the profession, to the public and to patients. I wish to call attention to only a few of these specific obligations which are set forth in this booklet which should be fulfilled by all ophthalmologists. The first is:³

The obligation assumed on entering the profession requires the physician to comport himself as a gentleman and demands that he use every honorable means to uphold the dignity and honor of his vocation, to exalt its standards and to extend its sphere of usefulness.

Read before the Section on Ophthalmology at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 4, 1941.

1. Principles of Medical Ethics of the American Medical Association, Chicago, American Medical Association, 1940.

2. Principles of Medical Ethics, p. 3.

3. Principles of Medical Ethics, p. 6.

The second obligation⁴ is a rule of conduct relating to rebates. It is stated thus:

It is unprofessional to accept rebates on prescriptions or appliances, or perquisites from attendants who aid in the care of patients.

The third obligation, which relates to "profits to lay groups" is stated thus:⁵

It is unprofessional for a physician to dispose of his professional attainments or services to any lay body, organization, group or individual, by whatever name called, or however organized, under terms or conditions which permit a direct profit from the fees, salary or compensation received to accrue to the lay body or individual employing him. Such a procedure is beneath the dignity of professional practice, is unfair competition with the profession at large, is harmful alike to the profession of medicine and the welfare of the people, and is against sound public policy.

And finally⁶

the duty of the physician to his patients, to other members of the profession and . . . as well as to . . . the public

is stated thus:

It is incumbent on the physician that under all conditions, his bearing toward patients, the public and fellow practitioners should be characterized by a gentlemanly deportment and that he constantly should behave toward others as he desires them to deal with him. Finally, these principles are primarily for the good of the public, and their enforcement should be conducted in such a manner as shall deserve and receive the endorsement of the community.

Let me call your attention also to the following resolutions, which were adopted by the Section on Ophthalmology of the American Medical Association at the Chicago session in June 1924. These, however, were not presented to the House of Delegates.

Resolved, That it is the sense of the Section on Ophthalmology of the American Medical Association that we deprecate the selling of glasses by the ophthalmologist to his patients, in communities where the services of reliable dispensing opticians are obtainable; and

Resolved, That the acceptance of commissions or considerations, either directly or indirectly, from opticians and optical houses, from the sale of glasses is absolutely contrary to all our standards of medical ethics and is just as reprehensible as the splitting of fees.

These principles of ethics and the resolutions adopted by this section present the obligations which the profession regards as the minimum ethical standards of practice for ophthalmologists. From the information which I have been able to gather I fear that these standards are more "honor'd in the breach than in the observance."

The situation which is peculiar to ophthalmologists consists in the fact that the correction of errors of refraction constitutes a large percentage of his practice—from 60 to 90 per cent; and ophthalmic lenses and their mountings must be supplied and properly fitted to each individual when a correction is prescribed. This requires some form of commercial relationship with those nonmedical men who render this service. Another situation peculiar to the practice of ophthalmology is competition with optometrists in the service of correct-

ing errors of refraction. In many communities the fee of the ophthalmologist for making the ocular examination, including that of refraction, is less than the profit made by one who furnishes the prescribed glasses. Very often too, when the prescription falls into the hands of the optometrist the patient likewise falls into his hands. The degree of cooperation between ophthalmologist and optometrist leaves very much to be desired. The advertising and the activities of the publicity agents of the optometrists place at a disadvantage the ethical ophthalmologist who does not, will not and should not employ these methods to secure favor with a price conscious public, easily influenced by the wiles of the advertiser.

METHODS OF SUPPLYING GLASSES

Let us now analyze the methods, commonly employed, by which glasses are supplied and then point out briefly the ethical principles involved in the use of each method. There are at least six different methods for supplying the correcting glasses, which are as follows:

1. The first method is that in which the ophthalmologist gives the prescription for the lenses directly to the patient, who is instructed to have it filled by any reliable optician of his own choice. Should the patient request the ophthalmologist to recommend an optician, such recommendation is usually made. It is customary for the ophthalmologist to make an inspection after the prescription is filled. For the entire service of supplying a prescription and inspection the ophthalmologist receives a single fee and no other remuneration either directly or indirectly. In the use of this method he does not accept any rebate, "kick-back" or any part in the profit from the glasses provided.

2. By the second method the ophthalmologist personally furnishes the glasses. He does this either by means of an optician's laboratory, connected with his office, or by having the prescription filled and mounted by a dispensing or jobbing optician, the completed job being delivered to the ophthalmologist, who makes final inspection and adjustment, the ophthalmologist charging and collecting the prevailing retail price of the glasses in addition to his fee for examination. This is a direct and open and ethical transaction between doctor and patient.

3. By the third method the prescription is filled and the mounting completely fitted by a wholesale dispensing optician, who charges a nominal fee for the extra service of adjustment of mountings and collects the prevailing retail price for the completed work. This leaves a differential in cost between the wholesale price plus service charge and the retail price, and this differential—a profit—is credited to the ophthalmologist issuing the prescription. This method may or may not be known by the patient.

4. By the fourth method the ophthalmologist sends the patient to some chosen optician, who completes the entire work of filling the prescription, mounting, adjusting and collecting the full retail price, returning to the ophthalmologist a specified rebate, which is done without the knowledge of the patient. By some the prescription is not given to the patient but is delivered to the optician so that none may go astray.

5. The fifth method is one in which ophthalmologists have a partial or complete ownership in an optical dispensing store, which at times is designated by the more subtle name of laboratory. By this method the

4. Principles of Medical Ethics, p. 8.

5. Principles of Medical Ethics, p. 21.

6. Principles of Medical Ethics, p. 24.

ophthalmologist has a direct interest in the profits from sales connected with his prescriptions. The financial interest in such stores is generally not known to the patients who patronize such stores on advice of the ophthalmologist.

6. There is a sixth method. There are a few instances in which a physician with little knowledge of ophthalmology contracts for his services on a salary or on a percentage basis to some retail establishment where both the examination and the sales are conducted.

COMMENT

The first method is the ideal, ethical one; its employment is in harmony with the resolution of this section. It removes the possibility of any selfish interest or bias in the transaction of supplying glasses. This is the highest ethical form of practice and is followed by the leading ophthalmologists in the United States.

The ethics of the second method hinges on the question, under certain given circumstances of location or of availability of dependable opticians, whether adequate optician's services can be obtained. That service which has the best interest of the patient in mind is the one which should be employed; in many localities the ophthalmologist must perform the fitting and adjusting services usually rendered by the retail or dispensing optician. There is nothing unethical about this form of practice if all financial transactions are open and understood by the patient. And there can be nothing unethical in charging the established retail price for the quality of the glasses supplied, when the services of fitting, checking and adjusting are performed by the ophthalmologist. He also assumes the responsibility of the financial transactions.

The third method, the one in which the wholesale dispenser furnishes the glasses and makes some nominal charge above the wholesale price, performs the service of adjustment, inspection and collection but credits the ophthalmologist with a differential, is open to criticism, especially when no additional service is rendered for the differential, which is, of course, a rebate. And this practice is particularly reprehensible when it is done secretly.

There can, of course, be no justification whatever for the receiving of a percentage rebate for glasses which are furnished by opticians who provide all the services connected with the supplying of glasses. This practice violates every ethical medical principle of practice. Under these circumstances the patient either receives an inferior quality of product or an inferior optical service.

The outright or partial interest in any retail optical store is an indirect method of receiving rebates, and the best ethical traditions of the profession are violated when ophthalmologists yield to this temptation to make a profit on ophthalmic supplies.

The practice of selling one's services to some lay body is a direct violation of the physician's obligation to the profession, as I have shown in the quotation from the Principles of Medical Ethics. This practice fortunately is seldom followed. No self-respecting ophthalmologist should be guilty of this unethical practice.

It is a fundamental duty of the ophthalmologist to give to his patients an unselfish, unbiased and unhampered service—the best advice which his experience and knowledge dictate. It is very questionable whether such

service can be rendered without some degree of prejudice, perhaps unconsciously, by an ophthalmologist who has a financial interest in the commercial side of supplying the equipment. As far as refractive problems are concerned, patients consult the ophthalmologist not primarily to get a pair of lenses but to find out whether or not there is need for them. The answer to that problem should be answered without any bias.

It seems to me that the crux of unethical practices lies primarily in some secret form of rebate, differential or kick-back—to some furtive participation in the profits connected with the supplying of lenses and their mountings, which participation is done without the knowledge of the patient. As a consequence of this method of practice, patients are compelled to pay for services which are not rendered either by the ophthalmologist or by the optician. Evidently this practice does not consider the best interest of the patient.

When an adequate and proper fee is made for the professional services rendered, the ophthalmologist is not ethically entitled to some additional fee from the sale of the glasses. When any rebate method is practiced, by whatever name it is designated, which method requires the optician to split the profits with the ophthalmologist, it is probable either that an inferior quality of ophthalmic goods is supplied or that the optician's service is lacking in high standard. All rebates are a form of fee splitting which cannot be defended on any ethical ground. There can be no justification for trading on the confidence of the patient openly or secretly, but the secret practice is the more reprehensible. These forms of unethical conduct are emphatically condemned by the medical profession, and those who practice them are bringing disrespect, derision and dishonor to the profession.

In an address delivered at a recent meeting of the Medical Society of the County of Monroe in New York State, Dr. Van Etten, President of the American Medical Association, said that organized medicine had always upheld the highest ethical standards and "The parent organization has never sold us down the river because of any form of commercial or legislative pressure." Surely the Section on Ophthalmology of the parent organization will not be the exception to this ethical history. No ophthalmologist should be guilty of participation in the secret distribution of profits in the supplying of glasses, nor should he be guilty of trading on the confidence of his patients. Every ophthalmologist should conduct his practice and his relationship with lay bodies so that he will serve the best interests of the public, the patients and the profession. Only in this way will he help to remove the indictment against ophthalmologists and help to maintain the good repute of our honored profession at its historic ethical standard.

53 South Fitzhugh Street.

Galen Made a Mistake.—Galen in his role as an anatomist insisted that the physician should be a dissector, which was a revolutionary idea. He apparently never dissected the human body. He did dissect many types of mammals, birds, reptiles and fish and prepared the bodies of monkeys for anatomical study. He made the mistake of affirming that all animals, including man, were absolutely identical in their organic parts. Apparently he was struck by similarities rather than differences, a trap in which many modern observers are caught.—Lewis, Nolan D. C.: *A Short History of Psychiatric Achievement*, New York, W. W. Norton & Co., Inc., 1941.

OCCULT FRACTURES

ROLAND HAMMOND, M.D.

PROVIDENCE, R. I.

AND

DENIS S. O'CONNOR, M.D.

NEW HAVEN, CONN.

This paper has been written from the point of view of the practitioner who is forced to depend on inadequate facilities for roentgen ray diagnosis. In many otherwise excellent hospitals the visiting roentgenologist attends the hospital once a week and reads all the films taken during the previous week. During his absence the physician is obliged to depend on the diagnosis of a technician or on his own judgment.

We wish to emphasize the importance of the clinical examination for a suspected fracture in the face of a negative verdict by roentgen ray examination. Both examinations should be employed, but in case of doubt the clinical examination should prevail.

There is need of improved education of roentgen ray technicians, better training of the practitioners in the reading of roentgenograms and more cooperation between the physician and the roentgenologist.

The one surgical condition in which the roentgen ray examination as a diagnostic agent might be considered well nigh infallible is fractures. Yet even at this time of relatively advanced roentgen ray technic there are fractures which may be diagnosed clinically in spite of negative roentgen ray findings. We have chosen to call such fractures "occult fractures."

An occult fracture may be defined as one which gives clinical signs of its presence yet which, with excellent roentgen ray technic, cannot be demonstrated by the roentgen ray examination before reparative changes have taken place.

It is, of course, not uncommon to fail to disclose fractures by the roentgen ray examination because of faulty technic or insufficient posturing, and while some

inestimable help in the diagnosis and treatment of fractures, but it is not the last word in diagnosis, although in the opinion of the public and the courts and, we regret to say, in the minds of many medical men it is accorded a place in diagnosis much more prominent than is rightfully to be expected.

For many years roentgenologists have recognized that certain fractures of the ribs, skull and spine could not be diagnosed by any technic known at the present time. This list must be enlarged to include other bones, as we shall demonstrate later.

Watson-Jones,¹ referring to fractures of the carpal scaphoid, says:

Negative x-ray findings do not exclude a recent scaphoid fracture. . . . The clinical diagnosis of a recent fracture of the scaphoid, based on the history, the effusion into the joint and the localized tenderness, is sometimes more accurate than the x-ray diagnosis. Radiographic evidence is by no means infallible. Films of perfect quality taken on the day of injury may show no evidence of the fracture which has been sustained. If the clinical features suggest a probable fracture, but the anteroposterior and oblique radiographs show no evidence of it, the x-ray examination must be repeated two or three weeks later.

Fig. 2 (case 2).—Periosteal thickening of third metatarsal bone of several weeks duration.

Now fractures which cannot be demonstrated by the roentgen ray examination may be considered to be relatively unimportant, which is generally true, but unexplained symptoms are commonly the cause of a great worry to the patient, the source of great expense in the search for an explanation of the pain and the source of great economic loss, especially if the patient is an industrial worker.

The subject has a medicolegal significance, since at least one suit for malpractice has been instigated for the improper treatment of a fracture of the clavicle which was not diagnosed at the first roentgen ray examination.

REPORT OF CASES

CASE 1 (fig. 1).—A young woman² sustained a contusion of her knee in an automobile collision. Roentgenograms of the knee taken shortly afterward were reported negative for fracture. Because of persistent pain and swelling, new roentgenograms were taken several weeks later, no new injury having occurred, and a definite stellate fracture of the patella was found.

CASE 2 (figs. 2 and 3).—A student² at Yale University reported at the orthopedic department, complaining of a painful foot of several weeks' duration. He could not remember any injury. The dorsum of the foot in the metatarsal area showed a moderate diffuse swelling. Pressure over the shaft of the third metatarsal bone was painful, and the bone showed definite

Fig. 1 (case 1).—Occult fracture of the patella: A, shortly after accident; B, appearance several weeks later, showing stellate fracture of the patella.

of the cases here reported may fall into that category we would emphasize that the roentgen ray still is not infallible in the diagnosis of fractures.

The roentgen ray examination is essentially a laboratory procedure and should never be permitted to obscure the clinical examination and point of view. It is of

thickening at this point. A roentgenogram was taken which revealed enlargement of the third metatarsal bone at the point complained of due to periosteal reaction. No fracture line could be made out. Under mild metatarsal support the symptoms subsided within a few weeks.

CASE 3.—M. L., a middle-aged woman,² stumbled and fell on June 14, 1940. She got up and continued on her way. Three months later because of continuation of pain in the foot she consulted a doctor, who hospitalized her for six days but did not make any roentgen ray examination. She continued to favor the foot because weight bearing was painful. She was first seen by one of us on Nov. 2, 1940 for a complaint of pain in the instep of the right foot. Examination revealed tenderness over the distal end of the third metatarsal bone. Roentgenograms of the foot which had been made before consulting us and which had been reported to be negative for bone injury were studied. Careful examination revealed a small area of localized periosteal proliferation on the dorsum of the distal end of the third metatarsal bone. Under a mild support applied to the metatarsal arch the symptoms were relieved.

CASE 4 (figs. 4 and 5).—A. A. B., a woman³ aged 70, in January 1928 was in an automobile accident and was thrown to the right side of the car with her head and neck twisted backward. She was rendered unconscious. On regaining consciousness she complained of pain over the right clavicle. She was taken to a capable surgeon, and roentgenograms by an excellent roentgenologist in two planes⁴ revealed no fracture. The arm was partially immobilized. Three weeks after the accident she felt sudden pain and crepitus just lateral to the middle of the clavicle with pain down the arm to the elbow. She requested another roentgen ray examination, which showed a fracture at the point mentioned with upward displacement and firm callus formation. There was pain on any movement of the right shoulder. She was seen by one of us thirteen weeks after the accident, and the deformity described was observed. Union was firm with considerable callus present. Shoulder motions were painful but not limited. Operative reduction was advised but declined. She was fitted with shoulder straps with some relief of pain. She died two years ago with the deformity still present.

CASE 5.—H. S., a woman⁵ aged 35, on Sept. 7, 1931 was thrown against the side of an automobile and injured the region of the left clavicle. She was taken to a hospital, where a roentgen ray examination revealed no injury to the clavicle. The shoulder was strapped and a sling applied. One week later she consulted one of us complaining of a tender, bony

report this case, fell from a tree on July 27, 1937 and injured his right shoulder region. He was given emergency treatment for a fractured clavicle and taken to a hospital, where a roentgen ray examination showed no fracture. He was referred to Dr. Harris, who made another roentgen ray examination and again no fracture was seen. Nevertheless the arm was placed in a Velpeau bandage and the elbow lifted. On September 3 he

Fig 4 (case 4).—Occult fracture of right clavicle as it appeared on day of injury.

was examined by one of us (R. H.) in the absence of Dr. Harris. There was a forward projection at the middle and inner thirds of the right clavicle. Firm union was present with considerable bony thickening. The right clavicle measured $\frac{1}{4}$ inch shorter than the left. The distal fragment was slightly overriding and projected under the skin as a sharp point. Roentgen ray examination showed a longitudinal fracture with some overriding and a transverse fracture as well at the middle and outer thirds of the clavicle. The patient was seen by Dr. Harris on September 17 and the same condition was present. The sharp spicule under the skin caused no redness or discomfort.

CASE 7 (figs. 6 and 7).—M. O'B.,⁵ seen Aug. 20, 1927, fell while running and injured her left wrist. The wrist showed considerable swelling about the radial styloid, but no silver fork deformity was present. No fracture could be made out by roentgen ray examination. Manipulation of the wrist under anesthesia was advised, in spite of the negative roentgen ray findings. During this procedure considerable crepitus was felt and the swelling disappeared. Postreduction roentgen ray examination revealed a Colles fracture with the fragments in perfect apposition. Convalescence was uneventful and she was discharged October 4 with complete function, and roentgen ray examination showed accurate position and firm union.

We have discovered 6 cases showing fractures of the clavicle without displacement. These occur at the point where the shadow of the clavicle and that of the first rib intersect, which renders interpretation of the roentgenogram difficult. These cases are not reported in detail.

The following cases are reported for purpose of record, although we regret that they cannot be verified, since it is impossible to locate the roentgenograms:

CASE 8.—A young Italian girl² came to the orthopedic clinic of the New Haven Hospital complaining of pain in the metatarsal bone of the foot, especially on weight bearing. She

Fig. 3 (case 2).—Lateral view of foot.

prominence over the middle of the left clavicle. A roentgenogram revealed an oblique fracture of the clavicle at this point with elevation of the outer fragment. Shoulder straps and a sling were applied, and she was discharged on October 30 with no deformity, solid union of fragments, and free shoulder motions.

CASE 6.—J. H., a boy aged 11, seen in the practice of Dr. Herbert E. Harris of Providence, who has allowed us to

3. A patient of Dr. Hammond
4. Phillips, Herman B: A Lateral View of the Clavicle, *J. Bone Joint Surg.* 17: 202 (Jan.) 1935
5. Reported by Dr. Hammond

could not recall any injury. Examination of the foot showed a definite but diffuse swelling on the dorsum of the foot. Tenderness was maximum over the shaft of the third metatarsal bone. Pressure beneath the head of the third metatarsal bone was

Fig. 5 (case 4) — Fracture of right clavicle as it appeared thirteen weeks after the accident.

productive of pain. Extreme passive dorsiflexion or plantar flexion of the third toe was painful. A clinical diagnosis of fracture of the third metatarsal bone was made and a roentgenogram was ordered. The roentgenogram was reported to be

Fig. 6. (case 7) — Occult Colles fracture of left wrist. A, anteroposterior view; B, lateral view.

negative for fracture, and a study of the films failed to reveal any fracture. Several weeks later another roentgenogram was taken which clearly revealed a fusiform periosteal reaction about the shaft of the third metatarsal bone. On the basis of the periosteal reaction the roentgenologist concurred in a diag-

nosis of a fracture of the third metatarsal bone. The patient went on to complete relief of the symptoms for which she came to the clinic. Unfortunately the films of this case are not available.

CASE 9.—A middle aged woman² while walking experienced a sudden sharp pain in her foot. Continuation of the pain for several days forced her to seek medical care. A diagnosis of a fracture of the shaft of the third metatarsal bone was made from the localized tenderness. With special attention to the technic of bringing out bone detail a fine fracture line was found in the shaft of the third metatarsal bone.

CASE 10.—A young woman,² dietitian in the New Haven Hospital, twisted her ankle while walking but continued her activities and did not seek immediate medical aid. Several weeks later because of continued pain and slight swelling about the lateral malleolus of the ankle she consulted an orthopedic surgeon, who requested roentgenograms. These showed a mild

Fig. 7 (case 7).—Appearance after reduction. A, anteroposterior view; B, lateral view.

periosteal proliferation about the distal end of the fibula but no fracture line. The possibility of an early malignant growth was strongly considered but the condition went on to complete subsidence of symptoms within a few weeks. The roentgenograms of this case could not be located at this time.

CASE 11.—D. R. B.,² seen Aug. 6, 1938 with a history that he stubbed his fourth right toe against a bedpost, noticed pain and swelling at the base of the second, third and fourth toes and pain limited to the fourth toe. Roentgen ray examination showed a transverse fracture of the midshaft of the proximal phalanx of the fourth toe but no fracture elsewhere in the foot. He was treated for a fracture of the fourth toe and disappeared from observation after two months of treatment and did not return until October 28. At this time he complained of pain over the second metatarsal bone, where there was considerable thickening and tenderness. Roentgen ray examination showed evidence of a fracture behind the head of the second metatarsal, with marked callus formation. The fracture line in the proximal phalanx of the fourth right toe had disappeared with firm healing.

CASE 12.—A young man² was referred to one of us by his physician because of a persistent pain in the shoulder, which had been present since an automobile collision in which he was involved. Roentgenograms had been taken and reported to be negative for fracture. New roentgenograms were taken which revealed a longitudinal split in the distal third of the clavicle. Under rest and protection for the shoulder the condition cleared up after several weeks.

It might be argued that convincing evidence of roentgen ray failure has not been shown in some of the cases presented, and our failure to present immediate roentgenograms showing no fracture and later roentgenograms showing the periosteal reaction or repair in other cases does not permit disinterested observers to check our report, rendering many of the cases which we have presented as worthless in proving our contention; however, we are convinced that even the small number of acceptable cases of occult fractures presented here does warrant the recognition of occult fracture as a clinical entity.

The location of the occult fractures presented is such that no technical difficulties to the optimum demonstration of a pathologic condition of bone are present, except in the case of fractures of the clavicle.

It is obvious that in those regions of the body in which demonstration of a pathologic condition of bone by roentgen ray examination is difficult because of the distortion of the parts and the irregularity and overlapping of other bones or parts of bones, occult fractures could occur with little if any chance of detection.

One has but to refer to the comparison between the clinical roentgen ray finding in fatal traumatic cases and the findings at the postmortem examination to convince oneself that, if fractures which are not occult cannot be demonstrated, occult fractures certainly may be present and missed in large numbers.

The conception of the occult fracture is offered in the belief that it will prove to be a useful explanation of otherwise unexplained symptoms.

CONCLUSION

In dealing with fractures we should be clinicians first. We should welcome any help that roentgen ray examination can give us but should never allow it to befog our judgment when the clinical findings are at variance with the interpretation of the roentgenogram.

More emphasis should be placed on the clinical examination of a suspected fracture, and the result of this examination should be checked by a study of the roentgenograms.

In case of doubt the injury should be treated as a fracture. The condition should be explained to the patient, and the reason for such treatment made clear. If such a procedure is carried out, I believe most causes for criticism will be removed.

Furthermore, the fracture surgeon should be able to interpret the roentgenograms himself or in collaboration with the roentgenologist. It is only by association of the clinical and roentgen ray findings that a proper interpretation of the injury can be attained.

In a letter to the *Lancet* in 1908 Sir Robert Jones⁶ said:

While Roentgen's discovery has been to us of immense value, chiefly in the classification of our injuries, it has done little if anything to perfect or even alter our treatment of fractures. It is a valuable adjunct to our clinical armamentarium, but it should not be allowed to usurp our other diagnostic faculties. It is deplorable to think of the education of the student today,

who rarely troubles to make himself ordinarily efficient in the diagnosis of a fracture but meekly awaits the revelation of an often misleading roentgen ray photograph.

What was true in 1908 is true in 1941.

219 Waterman Street, Providence, R. I.—158 Whitney Avenue, New Haven, Conn.

ABSTRACT OF DISCUSSION

DR. WALTER C. HILL, Cleveland: By the authors' definition "an occult fracture is one which the roentgenologist fails to find." Over a period of years I have tried to perfect my technic so that these failures are brought to the minimum. These principles are: 1. A roentgen ray tube of the finest focal spot obtainable. 2. Nonscreen film technic whenever possible, or fine detail intensifying screens where screens are required. 3. Proper density of roentgenograms; for example, films made of the hands and feet should be sufficiently dark to require study by the spotlight and should be studied with a magnifying glass. 4. Immobilization of the patient, achieved by judicious use of sandbags and restraining bands. 5. Extra views in all cases in which experience has indicated that fractures are commonly overlooked; for example, special carpal views for scaphoid (navicular) fractures. Special elbow views for the radial head or olecranon; extra angle views of the ankle for fractures about the malleoli; extra vertical and angle views of the shoulder for clavicle study. Routine stereoscopic views of the skull, shoulders, spine, pelvis and hips. 6. Careful clinical examination by the roentgenologist before the patient is dismissed as negative to make sure that all possible variations and positioning in technic have been employed for the case being examined. Recently I reviewed 10,485 wrist examinations in my private practice. There were 2,494 Colles fractures, 534 recent scaphoid fractures and 93 old ununited scaphoid fractures. As an example of the value of cooperation between the clinician and the roentgenologist, in one of my offices where I work in close collaboration with several industrial surgeons I find 1 scaphoid to 3 Colles fractures, while in the other office, where most of the patients are referred by general practitioners, I find only 1 scaphoid to 7 Colles fractures. This indicates clearly that clinicians can be trained to become scaphoid conscious and not overlook these important injuries. One may agree in part with Drs. Hammond and O'Connor that in certain cases the clinical evidence should take precedence over negative roentgen ray findings, most certainly if the roentgen examination is done in a routine or perfunctory manner without the collaboration of an experienced roentgenologist. But Sir Robert Jones and the authors to the contrary, I cannot agree that the value of the roentgen ray in the diagnosis and treatment of fractures has not altered since 1908.

DR. CHARLES N. PEASE, Chicago: The so-called occult fractures are extremely rare. I feel that more of these fractures are not demonstrated in the roentgenogram because a sufficient number of views are not taken. This does not hold true with roentgenologists like Dr. Hill, but for the most part it does. For suspected fracture of the carpal scaphoid, for example, at least films of six different positions of the wrist should be made. Fractures of the other bones are sometimes difficult to visualize, such as the tarsus, metatarsus and clavicle, head of the radius, vertebra and scapula. We are all familiar with these and are agreed that universally improved roentgen technic will go a long way in demonstrating these fractures. Before the days of improved roentgen technic, fractures of the body of the vertebra with little or no displacement were not recognized and collapsed on weight bearing. These fractures, as you know, were called "posttraumatic collapse of Kummel." It is true that if one takes several views of the ankle showing a trauma there may be no roentgen ray evidence of fracture, but after six weeks the cortex of the lower end of the fibula may show some new bone formation. This may be due to unrecognized fracture or periosteal elevation. If there was a great amount of pain and swelling, immobilization, of course, would be employed whether or not a fracture line was demonstrated. To prove the existence of these occult fractures, postmortem examination or animal experimentation will remove all doubt as to their existence.

⁶ Jones, Sir Robert: Letter to Editor, *Lancet*, March 21, 1908, 1, p. 888.

DR. ROLAND HAMMOND, Providence, R. I.: I agree with everything that has been said. My object in the paper is educational. Picture the condition of the average general practitioner in a small community with a good local hospital—the technician, who has been trained by some other technician, and the visiting roentgenologist, who appears once a week. The fracture occurs the day after this roentgenologist has visited. The doctor accepts the diagnosis of the technician, and before the roentgenologist gets around the next week the harm has been done; therefore, it seems to me, a campaign should be instituted for help to the practitioner. Those of us who are interested in fracture work know that more than two views of an ankle are necessary. We know that a lateral view of the clavicle should be taken, but nevertheless there are other fractures. You must all have had the experience at autopsy in a traumatic case of having the pathologist tell you "Well, he had a fracture of so-and-so, but then you couldn't have seen it anyway." More should be done to make it easier for the man who has access to inadequate roentgen ray facilities.

THE ELECTROLYTE THERAPY OF PREMENSTRUAL DISTRESS

J. P. GREENHILL, M.D.

AND

S. C. FREED, M.D.

CHICAGO

Premenstrual tension is the term which Frank has designated for a not uncommon syndrome which occurs in the premenstrual phase and disappears with the onset of menstruation. It usually consists of several of the following symptoms and signs: headache, emotional instability, irritability, abdominal distention, nausea and vomiting, increased sex desire, pruritus and swelling of the vulva. Many women, however, suffer from moderate degrees of such disturbances but these are usually accepted without question as a normal feature of the menstrual cycle. For the sake of convenience we have termed the latter condition "premenstrual distress." It is our belief that both premenstrual distress and premenstrual tension have a common etiology, the difference between the two being a quantitative one. We have postulated that both are the result of changes in the electrolyte and water balance of the various tissues of the body which are probably the result of cyclic ovarian activity. Thus, under the influence of certain ovarian steroids, sodium is retained by the tissues with a subsequent increase in extracellular fluid. When this occurs to a significant degree in the brain, headaches develop; when the gastrointestinal tract is involved, distention occurs, and, when the edema is located in the skin of the labia, pruritus may appear. With the subsidence in activity of the ovary coincidental with menstruation, the various tissues lose their retained sodium and water and the respective symptoms disappear.

On the basis of our theory we¹ administered ammonium chloride for therapeutic purposes in order to prevent the retention of sodium in the tissues. Following this therapy for 15 patients suffering from premenstrual distress or tension we observed almost uniform relief of symptoms. We have considered these results as evidence in support of the hypothesis that premenstrual distress or tension is due primarily to sodium retention. In the present paper we are report-

ing the results of the treatment of 40 patients suffering from premenstrual distress or tension with ammonium chloride.

METHODS AND RESULTS

The disturbances which appeared most frequently in our cases of premenstrual distress were headaches, nervous irritability, abdominal distention and nausea. Less commonly some women experienced increased sex desire, edema of the vulva and a feeling that the skin was tight. Four patients were considered to have premenstrual tension because of the intensity of the symptoms. These patients presented marked emotional instability with behavior changes consisting of depression, excitation, "temper tantrums" or "crying spells." Four patients demonstrated subcutaneous edema, excluding those with vulvar edema. One patient, a physician's wife, gained 7 to 8 pounds before each menstrual period, which was lost after the flow.

Ammonium chloride was administered in doses of 3 Gm. daily, divided in three doses, starting ten to twelve days before the expected menstrual period. In order to limit the sodium intake somewhat, patients were asked to refrain from using table salt or sodium bicarbonate preparations.

Thirty-four of the 40 patients had definite relief from the usual premenstrual disturbances. These patients stated that they had an increased sense of well-being at this time in addition to freedom from distress. It was interesting to observe that many of the patients on ammonium chloride therapy were unaware of an impending menstrual period, which they could formerly predict a number of days in advance. The relief of symptoms was most gratifying for those patients suffering from the severe forms of premenstrual distress. Here the results were quite dramatic. Those patients who usually suffered from abdominal distention or visible edema failed to do so after therapy. Relief from all types of disturbances was obtained in subsequent cycles, provided the electrolyte therapy was continued. The administration of ammonium chloride was of little use in alleviating migraine unrelated to the menstrual cycle, dysmenorrhea or painful breasts.

COMMENT

It is well known that women frequently gain weight in the premenstrual phase and lose a corresponding amount during and following the menses. This fluctuation in weight is acknowledged to be the result of cyclic retention and loss of water. Thorn and his associates² have demonstrated that the retention of water during the premenstrual phase in normal women and those exhibiting premenstrual edema can be accounted for by sodium retention. There is considerable evidence that this response is induced by ovarian steroids. Thorn and Emerson³ have concluded that "premenstrual edema is probably the result of normal cyclic changes in sex hormone secretion acting on a precipitating factor in patients with some underlying change which predisposes to excessive retention of sodium chloride and water." These investigators have shown that a low sodium intake and the administration of potassium citrate prevents this retention of fluid.

In our opinion premenstrual edema is only one phase of the generalized sodium retention in the body and, because it is an involvement of the subcutaneous tis-

Read before the Section on Obstetrics and Gynecology at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 6, 1941.

sues, it is a visible phenomenon. We contend that internal organs of the body may undergo a similar change and the increase in water content manifest itself by the development of the various symptoms of premenstrual distress or tension. Ammonium chloride relieves the symptoms of premenstrual distress or tension by removing the extracellular fluid or "hidden edema" of such tissues in the same manner as it prevents the formation of premenstrual edema.

Several methods have been recommended for preventing or overcoming premenstrual tension. Frank,⁴ who first reported the treatment of this condition, obtained satisfactory results with the use of magnesium sulfate by mouth. According to this investigator, premenstrual tension is due to an increase in blood estrogens, and his purpose in using magnesium sulfate was to increase the elimination of the estrogens by the intestine. Such results as he obtained might, however, be satisfactorily explained by the dehydrating effect of magnesium sulfate. Israel⁵ has reported excellent results in cases of premenstrual tension by administering progesterone hypodermically during the premenstrual phase. Similar results have been claimed by Greenblatt⁶ for the use of testosterone propionate. From the results obtained by the latter two investigators it would appear that the ovarian steroids responsible for the development of premenstrual symptoms would be of the estrogenic type, since both testosterone and progesterone are capable of antagonizing many effects of estrogens. Israel observed an intensification of the symptoms of premenstrual distress following the administration of estrogens. Nevertheless, Atkinson and Ivy⁷ have reported successful prevention of premenstrual edema with an extract of the placenta whose active ingredient was estriol glucuronide. However, these investigators were unable to obtain similar effects with estriol itself. Thorn and Emerson suggest the possibility that progesterone or progesterone plus estrogens are the steroids responsible for premenstrual edema. Although further evidence is required before conclusions are justified as to the specific steroids giving rise to these conditions, it appears most likely that the responsible steroids are elaborated by the corpus luteum.

Ammonium chloride is not specific in the electrolyte therapy of premenstrual distress or tension. Other salts which can displace or withdraw sodium may be equally effective. Investigations are now being carried out by us to determine the efficacy of several such salts for their ability to relieve these conditions.

SUMMARY

We have found that ammonium chloride therapy is effective in relieving patients suffering from premenstrual distress or tension, the chief symptoms of which are headache, emotional instability, irritability, abdominal distention, nausea, vomiting, pruritus and swelling of the vulva. The hypothesis that this syndrome is the result of water retention in the tissues which gives rise to the specific symptoms is supported by the results of our treatment of 40 women and by evidence presented by other investigators.

ABSTRACT OF DISCUSSION

DR. JACOB KOTZ, Washington, D. C.: Premenstrual symptoms of depression, headache and gain in weight offer a problem which seriously handicaps the patient economically and socially. Since Dr. Greenhill's preliminary report, I have used ammonium chloride in several cases of severe premenstrual tension, headache, nausea and vomiting. The results have been gratifying and often spectacular. I have noted in the treatment of obesity that almost invariably there is a failure to lose weight and often quite a gain during the week premenstrually, even though the usual therapy was continued. A consistent loss of weight was attained by premenstrual administration of ammonium chloride. The sex sterols are involved in the salt and water metabolism, the disturbance of which leads to retention of water by the tissues. I question, however, whether estrogen is the sole factor. This is prompted by the fact that the bleeding induced in postmenopausal women by estrogen therapy is not preceded by tension or distress. The same is true for the few cases of anovulatory menstruation in younger women. It would seem, therefore, that the disturbance is in the estrogen-progesterone metabolism and that the presence of progesterone is necessary for the production of this phenomenon.

DR. KARL JOHN KARNAKY, Houston, Texas: The Menstrual Disorder Clinic, Jefferson Davis Hospital, Houston, Texas, has used ammonium chloride in 42 cases with uniformly successful results. Detailed chemical analyses of the blood are being studied in these cases. I have discovered a simple and efficient way to relieve premenstrual pelvic distress, dysmenorrhea and pelvic pains by the injection of 2 to 10 cc. of procaine borate or procaine hydrochloride into the anterior lip of the cervix, using a 10 cc. syringe and a spinal needle. Procaine borate, which has a pH of 8.5, is preferred to procaine hydrochloride, which has a pH of 3.5. By the injection of procaine, the pains in the pelvis are relieved immediately and in many cases are relieved throughout the menstrual flow. Eighty endometrial biopsies were obtained from 36 normal menstruating women and 6 women with functional uterine bleeding taking ammonium chloride. The 36 normal menstruating women all had a premenstrual endometrium, so ammonium chloride does not affect ovulation. The endometrium did not change in the cases of functional bleeding. In the 6 cases of functional bleeding there was less bleeding while ammonium chloride was being taken; so this may be another use for ammonium chloride. This will be studied further. Why does ammonium chloride work? Based on a new theory as to the cause of menstruation and labor, I am of the impression that it is due not only to the fact that edema is relieved but that, by reducing the sodium ion in the blood, one also increases the amount of potassium, magnesium and phosphorus ions, and especially the potassium. Potassium has much to do with functional activity of both the voluntary and the involuntary nervous system. Also the loss of sodium ions causes a less alkaline pH , with resulting freeing of the un-ionizable calcium ions. The increase in potassium ions apparently helps to conduct a normal impulse from the uterus to the brain through the autonomic nervous system. The administration of ammonium chloride by mouth favors a more ionizable calcium and favors shifting the pH of the blood toward the acid side. This shift in pH toward the acid side may cause the ratio of potassium to calcium to be normal, so more regular and synchronous uterine contractions; also the shift of the pH toward the acid side may cause the disappearance of the ill feeling that sometimes occurs premenstrually; or a slight alkalosis may be the entire cause of ill feeling at the menses. The ill feeling of menstruation has been produced experimentally by introducing alkalis into the anterior lip of the cervix.

DR. ESTHER B. TRIETZ, Cincinnati: Since Dr. Greenhill's first paper I have been interested to find whether ammonium chloride would help in the handling of psychotic patients. Many patients having manic-depressive psychoses and those with schizophrenic syndromes have outbursts of aggressive phenomena during the premenstrual and menstrual periods. This close relation between psychic activity and the ovarian cycle has recently been demonstrated by Dr. Benedek by accompanying the psychoanalysis of a patient with vaginal smears. We have found in some psychotic cases that there are autonomic disturbances directly related to the level of estrogenic content. It

would seem, therefore, that Dr. Greenhill's treatment might have some effect on autonomic activity. We have applied his treatment in cases in which postencephalitic crises were associated with the menstrual period and have been gratified at remissions in cases previously treated unsuccessfully by all known means. The patients themselves are enthusiastic because we have been able to send some home after prolonged hospitalization. Further testing and study will be necessary to learn what the action of ammonium chloride might be on psychomotor activity.

DR. J. P. GREENHILL, Chicago: Dr. Kotz emphasized a good point, namely that estrogen alone is probably not entirely responsible for the action of ammonium chloride, because the premenstrual tension does not occur at the height of follicular development. The change in water and electrolyte balance is probably due to the action of the steroids in the corpus luteum. Since it is highly likely that progesterone is not the responsible agent, the estrogens or the estrogens plus some other steroid of the corpus luteum may be involved. It was interesting to hear Dr. Tietz's remarks about the use of ammonium chloride for premenstrual and menstrual outbreaks in psychotic patients.

RAPID WEIGHT REDUCTION: LOSS OF THREE HUNDRED POUNDS IN EIGHTEEN MONTHS

REPORT OF A CASE

JAMES J. SHORT, M.D.

Associate Clinical Professor of Medicine, New York Post-Graduate
Medical School of Columbia University

NEW YORK

Questions which frequently present themselves to the practitioner confronted with the problem of reducing an overweight patient are: Can the weight be successfully reduced? If so, to what degree and how rapidly with safety? Despite repeated reports to the contrary, the impression lingers in the minds of many physicians that certain types of obesity are irreducible or so resistant to attempts at reduction that only a small amount of the excess weight can be removed.

NUTRITIONAL PRINCIPLES

There is probably no type of obesity, regardless of its cause, which will not respond by loss of weight to a submaintenance diet. Such a diet is one with a caloric value less than the daily expenditure by the subject. If a deficit can be thus successfully maintained, the body is compelled to draw on its own stores of fat for heat and energy. The problem, therefore, is to maintain a continued caloric deficit over a sufficient period to accomplish the desired result. Since metabolic adjustments are constantly being made in response to changing conditions, it is sometimes a bit difficult, though possible, to maintain such a deficit and at the same time to meet all the essential nutritional requirements.

There is no theoretical or practical reason for believing that not every bit of excess weight can be removed. This conception seems somewhat staggering when one considers the tremendous weights sometimes encountered. Nevertheless, the truth of this statement has been clearly demonstrated on numerous occasions. Therapeutic reduction of 239 pounds (118.4 Kg.) by medical means previously has been reported.¹ The patient has continued in excellent health and has maintained her weight at or near a normal level. Nor was her case unique, since the literature tells of other cases in which even larger amounts have been successfully removed.²

The question as to the rate at which weight reduction may be accomplished with safety is one on which there could be a wide diversity of opinion. Evans and Strang³ of Pittsburgh broke with more or less established medical tradition when they announced a plan successfully employed for rapid weight reduction. I have employed a similar regimen for a number of years with extremely gratifying results. Although it has not been found feasible or necessary to employ the extremely low diets of 300 to 400 calories mentioned by Evans and Strang, nevertheless a fairly rapid rate of reduction in weight has been found to hold out a much better prospect of success than the slow methods formerly employed. Morale, an intangible though important factor, is much better among patients who can perceive definite, consistent, weekly results. Theoretically, there seems to be no objection to the rapid oxidation of fat, provided essential dietary requirements are adequately met. Protein in an amount sufficient to replace daily that lost by metabolic processes is an absolute essential. To this end 1 to 1.5 Gm. per kilogram of ideal (not actual) weight should be provided. Approximately an equal amount of carbohydrate should likewise be given, although this should be varied according to the degree of adiposity at any one time. Strang, McClugage and Evans⁴ stated that 0.6 Gm. per kilogram of body weight is the minimal amount which can be employed to protect essential protein tissues of the body. However, if at all times one attempts to employ only the minimal requirement for purposes of protecting body protein, there will occasionally result in very obese patients an acidosis of the ketogenic type, since an amount sufficient to protect the proteins may in certain cases be inadequate to insure complete oxidation of the fats. As the daily caloric expenditure varies according to the degree of obesity, the huge breakdown of fat necessary to supply the required heat and energy may be so overwhelming as to produce acute ketosis if too little anti-ketogenic food is provided. I have seen this take place in a number of cases in which the overenthusiastic patient has taken less food than the diet provided. Fortunately, the occurrence of acidosis of this type is quickly corrected merely by the giving of sugar and other carbohydrates. If vomiting has ensued, as occasionally happens, the parenteral administration of dextrose may be required.

The reducing diet should contain a minimum of fat. Since the body has an excess of reserve fat readily utilizable, there is no point whatever to adding more fats to the therapeutic diet. Twenty Gm. of fat daily is about the minimum which I have been able to employ while meeting other requirements.

An adequate supply of vitamins is an important consideration in any reducing diet. Diets which I have frequently employed range from approximately 600 to 900 calories. Although it might be expected that the amount of A vitamin would be inadequate in a diet so low in fat content, the daily requirement is probably largely met through the use of green and other vegetables which contain its precursor, carotene. Since the diets employed contain citrus and other fruits, the danger of a C vitamin deficit is also avoided. The outstanding possibility of inadequacy is found in the B complex. A careful survey of reducing diets employed

in the Post-Graduate Nutrition Clinic and in private practice has indicated that the daily amount is definitely less than optimal. It is possible that the requirement with reducing diets is less than the average, since the amount of B₁ (thiamine) required is somewhat in proportion to the consumption of carbohydrates. Nevertheless, to insure against a possible deficit of this substance it has been my practice to add the B complex in concentrated form. No definite symptoms have resulted, however, in hundreds of patients who have been treated in the clinic with similar diets without the addition of the B complex. The amount of vitamin D in the diets employed is considered adequate.

Reducing diets can well contain considerable amounts of skimmed milk and cottage cheese, which are good sources of calcium. There is no need for the restriction of salt unless fluid is retained. Other minerals are largely provided by an abundance of vegetables of low carbohydrate content, as usually allowed.

Fluids need not be restricted unless there is a tendency to fluid retention. A routine restriction of fluids as practiced by many physicians is an unnecessary hardship if they provide no calories and the patient is in fluid equilibrium.

Metabolic stimulants have been previously discussed.⁵ The total basal heat production (i. e., the total caloric output on resting) increases directly with increasing weight. The extra heat required is produced by the vital tissues of the body, principally by the muscles. In very obese persons the caloric output per hour is prodigious. It is easy to approximate the calories of the daily maintenance diet consumed by such persons by multiplying the number of calories per hour, obtained when doing the basal metabolism test, by 24. This represents the basal (or resting) twenty-four hour caloric requirement. The addition of 25 per cent of this value for usual activity and specific dynamic action of food (a conservative estimate) will give approximately the number of calories required daily for maintenance. Practically, this determination is of great value for confronting persons who fail to lose weight on a prescribed submaintenance diet. When patients are shown scientifically that they are consuming food far in excess of the diet, confessions usually follow.

The case to be described is somewhat unusual because of the huge initial weight of 479 pounds (217.2 Kg.), wholehearted cooperation given for twenty months and the amount and rapidity of weight reduction.

REPORT OF CASE

History.—O. A., a woman aged 35, first seen on Dec. 30, 1938, complained of extreme obesity which dated from early childhood and a severe cough of five to six months' duration. She recalled that at the age of 14 she had weighed 200 pounds (90.7 Kg.); at 21, 260 pounds (117.9 Kg.), and at 31, 375 pounds (170.1 Kg.). She believed the reason for her overweight was simply the consumption of too much food.

Her father, who was 6 feet 1 inch (185.4 cm.) tall, had weighed 190 pounds (86.2 Kg.) and died of heart disease at the age of 51. Her mother, who was 5 feet 7 inches (170.8 cm.) tall, had reached a maximum of 220 pounds (99.8 Kg.) and died of disease of the gallbladder at 51. One living brother, 6 feet 1 inch (185.4 cm.) tall, weighed 200 pounds (90.7 Kg.). One living sister was extremely thin at 123 pounds (55.8 Kg.), and another sister was obese at 250 pounds (113.4 Kg.). There was no history of diabetes, but the father was thought to have had hypertension.

Fig. 1.—Patient at 479½ pounds (217.4 Kg.).

Fig. 2.—Patient at 250 pounds (113.4 Kg.).

Fig. 3.—Patient at 175 pounds (79.4 Kg.), after operation.

The patient performed no active physical exercise but was ambulatory. She had occasional edema of the lower extremities after standing but no varicose veins or symptoms referable to the arches. The joints were not painful. Headaches were frequent, and she had been told that her blood pressure was elevated. There were no digestive symptoms. The skin of the lower extremities had occasionally become ulcerated.

A marriage of fourteen years had resulted in one pregnancy followed by a spontaneous miscarriage thought to have been due to the strain of lifting. Her elimination was satisfactory and was occasionally aided by the use of magnesium sulfate. She ate sparingly of meat, eggs and fish and consumed no vegetables or cereals and little fruit. She drank four to five cups of coffee and one glass of milk daily but made up her huge intake of food by eating large amounts of cake and other baked foods. Although her regular meals were of moderate size, she ate at frequent intervals throughout the day. She used no tobacco, alcohol or drugs. She had had nocturia, urinating four or five times, and the menses, established at the age of 16, had always been irregular, with occasional

5 Short, J. J., and Johnson, H. J.: The Increased Metabolism of Obesity: Use and Abuse of Metabolic Stimulants, *J. A. M. A.* 106: 1776 (May 23) 1936. Short¹

absences of several months. She slept poorly because of her persistent cough and frequency of urination.

Her history was essentially negative for acute disease. There had been no operations.

Physical Examination.—On physical examination the patient weighed 479½ pounds (217.4 Kg.), with an estimated normal of 155 pounds (70.3 Kg.). She appeared to be fairly buried in thick layers of fat, as pictured in figure 1. The skin and mucous membranes were without blemish. The ocular muscles and fundi were normal. The tonsils had disappeared, and the teeth were in good condition. The thyroid gland was not palpable. The hands and the lymphatics were normal. The pulse rate was 80 and regular, the blood pressure 216 systolic and 130 diastolic and the cardiac sounds clear and of fair quality. The lungs gave forth numerous musical and sibilant rales of asthmatic type on inspiration and expiration, and there was a frequent irritative cough. The abdominal and pelvic viscera were impossible of palpation because of the extreme obesity. There was negligible edema of the lower extremities. Patellar reflexes could not be elicited because of fat.

at one-quarter, one-half and three-quarter hour periods respectively. The Wassermann and the Kahn reactions were negative.

The basal metabolic rate (calories per square meter per hour) was 22.1 per cent above the average normal. There was a total output under basal conditions of 126.9 calories per

Fig. 5.—Loss of 300 pounds (140.6 Kg.) in eighteen months by dietary and endocrine therapy. The diet was 600 to 800 calories, and from zero to 6 grains (0.4 Gm.) of thyroid was administered. Operation followed.

hour. Since the patient's theoretical average normal output at ideal weight was 63.7 calories per hour, this gave a figure of +99 per cent for the total heat production, which is practically double the normal (fig. 4).

The vital capacity was 1,500 cc., or 26 per cent of normal when calculated for the original weight. Calculated for the ideal weight, this would represent 43 per cent.

An initial electrocardiogram was not taken. One taken on Feb. 19, 1940, when the patient's weight was 197 pounds (89.4 Kg.), showed left axis deviation, so common in obesity, but no definite impairment. Initial fluoroscopic examination was not attempted, but on Sept. 25, 1939, when the weight was 257 pounds (116.6 Kg.) the total diameter of the heart was 15 cm. and there was evidence of slight ventricular enlargement.

Treatment.—Since it was thought that the patient was too lacking in self control to carry out a strict regimen at home, she was placed in a nursing home where she could be under constant supervision and dietary management. A diet of approximately 600 to 800 calories was prescribed in accordance with the principles already stated. Since it was calculated from her metabolic rate that a maintenance diet was approximately 4,000 calories, a diet of 600 to 800 calories would give a large deficit and result in a fairly rapid loss of weight. This occurred in accordance with expectations and is expressed graphically in figure 5.

After the loss of about 40 pounds (18.1 Kg.) the weight became stationary for one week because of the appearance of moderate edema of the lower extremities. This edema persisted in varying degrees throughout most of the period of reduction and was successfully combated from time to time by the use of ammonium chloride and mercurial diuretics. The intake of fluids and chlorides presumably was curtailed, but control was not perfect. After the patient had been for several weeks on the reducing diet, thyroid was administered to offset

Fig. 4.—Metabolism studies. Total calories per hour are at basal rate.

Laboratory Reports.—The urine showed a slight trace of albumin, with occasional hyaline and granular casts. The specific gravity ranged from 1.020 to 1.034. There was no sugar. The level of sugar in the blood as determined by the dextrose tolerance test was 117 mg. during fasting; at one-half hour, one hour and two hours after the ingestion of 100 Gm. of dextrose it was 125, 160 and 170 mg. respectively. At the one and the two hour period the patient voided 0.17 and 0.2 per cent of sugar in the urine.

The hemoglobin content was 14.2 Gm. per hundred cubic centimeters, or 104 per cent. The erythrocytes numbered 4,740,000. The value for urea nitrogen was 11.3 mg. and for nonprotein nitrogen 30 mg. per hundred cubic centimeters of blood, with a ratio of 37.5 per cent. The cholesterol content was 188 and the uric acid content 3.1 mg. per hundred cubic centimeters. The sedimentation rate was 7, 28 and 50 mm.

Fig. 6.—Type of incision in the plastic operation on the abdomen. A, before closure; B, after closure.

the reduction in metabolic rate which presumably had occurred from caloric restriction. Unfortunately, facilities were not available for metabolism tests at the nursing home.

The pulse rate varied from 74 to 100 for the first ten months and from 60 to 80 for the remainder of the period. The blood pressure became stabilized at an average level of from 120 to 136 systolic and from 60 to 80 diastolic. Vitamins were given in concentrated form throughout the reducing period.

Several complications ensued after 200 pounds (90.7 Kg.) had been lost. Dyspnea, weakness, nausea, excessive thirst and abdominal pain were noted on two or three occasions, at which times considerable acetone was present in the urine. These symptoms of acidosis were promptly checked by increasing the carbohydrates of the diet.

Within nine months the patient had reached 257 pounds (116.6 Kg.). She was permitted to return home to continue as an office patient. She did well for three months, but her weight became stationary at approximately 200 pounds (90.7 Kg.) after a loss of 279 pounds (126.5 Kg.). This weight persisted as a plateau for five months, as indicated in figure 5. At the end of that time she was hospitalized in the medical service of the New York Post-Graduate Medical School and Hospital, where she lost 17½ pounds (8 Kg.) in twelve days. Part of this weight was edema fluid in the lower extremities resulting from varicose veins.

At the end of the twelve day period she was transferred to the surgical service of Dr. Ralph R. Moolten for removal of excess skin from the abdomen and arms. His report follows:

"An abdominal panniculus hung in apron-like formation to about halfway down the thighs. Unless well trussed up with an abdominal binder this apron would interfere with walking. The under surface was excoriated by perspiration and by soiling with urine.

the skin was closed with interrupted silk sutures. Because of the diamond-shaped incisions at each end of the transverse one, the resulting final scar was H shaped. Enough skin was resected so that the incisions closed snugly but without undue tension. At all times during the operative procedure, the denuded areas were well covered with warm saline packs.

Fig. 8—Arm after operation.

Nevertheless, there was considerable reaction, manifested by a pulse which varied in rate, quality and rhythm. The patient left the operating table in fair condition. The postoperative course in the main was uneventful, complicated only by small areas of slough at each outer angle of the wound. The specimens of tissue weighed 6¾ pounds (3 Kg.) and consisted of skin and subcutaneous tissue alone, with practically no fat. Flatness of the abdomen even in the upright posture resulted.

"The next problem was a cosmetic procedure on the arms. When the arms were extended the skin hung in long, ugly folds from the axillas to the bends of the elbows. The method of outlining the incisions was to have the patient sitting on a table and leaning on her extended arms with the palms slightly behind her. On the mesial surface of each arm an irregularly club-shaped line of incision was delineated with an indelible pencil, covering an area approximately 11 by 4½ inches (28 by 11 cm.). As in marking out the abdominal incision, it was definitely ascertained that the cut edges could be approximated without undue tension.

"The wounds on the arms also were closed with interrupted silk sutures, and healing occurred by first intention."

Excess skin was subsequently removed from both thighs in similar fashion. The appearance of the patient before and after operation is shown in figures 7 and 8.

COMMENT

This case emphasizes again that there is apparently no limitation to the amount of excess weight which can be removed with perfect safety. It also indicates that in grossly overweight persons rapid weight reduction may be maintained over considerable periods without injury to health. During the first four months the patient lost 115 pounds (52.1 Kg.) at an average rate of 29 pounds (13.2 Kg.) per month. At the end of eight months she had lost 208 pounds (94.8 Kg.) at an average rate of 26 pounds (11.8 Kg.) per month, and at the end of twelve months she had lost 268 pounds (121.5 Kg.) at an average rate of 22 pounds (10 Kg.) per month.

The loss of so much supporting tissue over a short period brought with it certain complications, however. It was interesting to find that the patient had almost lost the power of locomotion after returning to her home. She was unable to climb steps but could walk short distances on the level. At this point she was told that she might expect a return of power to the affected muscles, since it was assumed that the removal of infiltrated fat had left the muscles relatively too long to be effective. The prediction proved true, and in a few weeks the patient was able to take up activities of

Fig. 7.—Patient before operation.

"At operation, instead of the usual elliptical incision from one anterior superior spine to the other, incisions were made as indicated in figure 7. The reason for the vertical incisions was to take up a large amount of redundant skin on the back and sides of the hips and thighs.

"With the patient under gas-oxygen anesthesia, the soft parts were resected down to the fascia. After suitable hemostasis,

housework and travel with practically normal facility. Another complication was the appearance of varicose veins, probably because of the loss of the supportive function of the subcutaneous fat. These will be treated surgically. In general health and mental attitude there has been a marked improvement. It is not uncommon for patients, when liberated from their prisons of fat, to express extreme gratification, and this patient was no exception.

Although initially the dextrose tolerance was definitely impaired, the patient was not classified as having diabetes. Poor tolerance of dextrose is frequently seen in obesity without diabetes, though the explanation of it is a problem.⁶ At the close of the periods of reduction the dextrose tolerance had returned to a normal curve, with figures of 106, 166, 182 and 111 mg. per hundred cubic centimeters during fasting, at one-half hour, one hour and two hour periods respectively.

The initial elevation of blood pressure and the subsequent restoration to a normal level also are not unusual, since obesity per se elevates blood pressure⁷ and reduction usually causes its diminution.

As to the cause of gross overweight in the case described, one cannot be too dogmatic. Undoubtedly, cases of such extreme obesity are rare, and for this reason one would expect to find some gross abnormality in glandular balance. It should be noted, however, that this patient had a basal metabolic rate which at +22 per cent was greatly in excess of normal and a total metabolism under basal conditions of twice the normal. It cannot be said, therefore, that she lacked the ability to oxidize foodstuffs. It can be asserted with every assurance that to maintain her weight she must have been consuming large amounts of food, probably to the extent of more than 4,000 calories daily. At the close of the period of weight reduction there was nothing to indicate that this patient had a glandular system in any sense abnormal. In the search for hormones which may have a direct or indirect effect on the metabolism of fat, the importance of insulin is often overlooked. Given to animals or human beings, this substance frequently results in spectacular increases of weight.⁸ It is not going too far afield to suppose that in certain persons the pancreas may be conditioned by diet or endocrine imbalance to produce a marked excess of insulin, with increased hunger and consequent obesity. It has further been shown⁹ that by abstention from carbohydrate foods the pancreas may be oppositely conditioned to a state of such extreme latency as to be unable to respond to sudden demands placed on it. This factor may in part explain the indifference to food frequently manifested by obese persons after becoming accustomed to a reducing diet.

SUMMARY AND CONCLUSIONS

1. In a case of extreme obesity, in which by therapeutic means were secured losses in weight of 115 pounds (52.1 Kg.) in four months, 208 pounds (94.8 Kg.) in eight months, 268 pounds (121.5 Kg.) in

twelve months and 300 pounds (136.1 Kg.) in eighteen months with an over-all average of 16 $\frac{2}{3}$ pounds (7.6 Kg.) per month, a total loss of 304 $\frac{1}{2}$ pounds (138.1 Kg.) was accomplished without any impairment in general health and with only a few minor adverse episodes.

2. Reduction in weight was accomplished by the use of submaintenance diets which averaged 600 to 800 calories and the careful administration of thyroid as a metabolic stimulant to offset the metabolism-depressing effect of such diets.

3. The restoration of blood pressure and dextrose tolerance to normal was a feature of this case.

4. The insulogenic factor has a possible role in the causation of obesity.

SHOULDER AND ELBOW LESIONS OF THE PROFESSIONAL BASEBALL PITCHER

GEORGE E. BENNETT, M.D.

Associate Professor of Orthopedic Surgery, Johns Hopkins
University School of Medicine

BALTIMORE

Every nation or tribe has a favorite sport in which its people often have more interest than they do in the many more serious vocations of life. The Americans, therefore, being no different from other peoples, have their own particular national sport—the American game of baseball. It has been my good fortune to study our pastime from many angles—as a player, as a fan and as a physician who has endeavored to rehabilitate or advise professional and amateur players.

Fig. 1.—Typical pitcher's shoulder. Appearance at the age of 24; this man began pitching professional baseball at 19.

Of all the members of a ball team, the pitcher is the hero and the player on whom most depends. On many occasions I have been asked to designate the type of shoulder lesion that is disabling to the professional baseball pitcher. My answer has always been that the professional pitcher is subject to all the disabilities of the shoulder to which the average person is, namely subacromial and subdeltoid bursitis, irritation of the

The study of the disabilities of the professional baseball player has been made possible by the cooperation given us by Mr. E. G. Barrow and Mr. George Weiss of the New York Yankees and their associated clubs; also Mr. Larry MacPhail of the Brooklyn Dodgers cooperated.

supraspinatus, irritation of the biceps tendon, traumatic synovitis and all the inflammatory diseases. Needless to say, his professional activities predispose him to the development of disability of the shoulder more frequently than one not engaged in an occupation which requires such excessive physical use of this articulation.

I believe that the symptoms and the pathologic changes of the so-called sore shoulder can be divided into two groups—the anterior and the posterior group. The anterior group, which is the most common, is composed of inflammatory and traumatic lesions of the supraspinatus tendon, the subacromial bursa, the subdeltoid bursa, the biceps tendon and the coracoid bursa.

Fig 2—The shoulder of a veteran pitcher aged 29

The rotation of the head of the humerus with its rubbing of the supraspinatus against the acromion may produce a traumatic irritation or a fraying of this tendon. This same motion may produce a similar condition of the biceps tendon. Lesions of the coracoid region are produced by trauma between the head of the humerus and

Fig 3—Typical exostosis of a pitcher aged 23

the coracoid process. At the finish of the "follow through," the arm is across the chest of the pitcher and the head of the humerus is pressed against the coracoid process, thus traumatizing the soft tissues between the head of the humerus and the coracoid process. The overhand pitcher irritates the supraspinatus, and the sidearm pitcher more often irritates the coracoid bursa

The symptoms of the lesions of the anterior group are sensitiveness about the point of insertion of the supraspinatus and a discomfort on abduction of the arm. When the biceps tendon is involved one notes a sensitiveness in the region of the bicipital groove and

Fig 4—Veteran pitcher aged 28. He also had osteochondritis of elbow, shown in figure 10

discomfort when the forearm is flexed against resistance. When these tendons are frayed by trauma actual crepitus may be elicited on active motion.

The treatment of the simple traumatic group is rest and local heat. When there is actual dissolution of the tendons, which become frayed, the biceps may respond to surgical treatment, but I do not feel that one could reconstruct a supraspinatus tendon and expect it to perform the strenuous and accurate function which

Fig 5—Detaching the posterior deltoid from the spine of the scapula

is required of a professional pitcher. Fortunately, the majority of the traumatic group of injuries respond to the orthodox conservative treatment.

If the history is that of an inflammatory lesion, a search for foci of infection should be made and the proper treatment prescribed. Since professional athletes are human beings, not supermen, general health often

Fig. 6—Exposure of the infraspinatus and teres minor muscles

plays a part in the disability and should be the first thought in the mind of the medical examiner. Frequently, infected teeth or tonsils cause or aggravate the

Fig. 7.—Exposure of the posterior capsule of the joint, the infraspinatus and the teres minor muscles are retracted.

so-called sore shoulder. Lesions of the inflammatory group respond to the removal of infection and to an improved general health regimen. Fortunately, one seldom sees a pitcher who is compelled to give up his

profession because of a lesion in the anterior shoulder region.

The lesions that occur in the posterior part of the shoulder are the ones which unfortunately shorten the career of the professional pitcher. In the past few years I have been able to demonstrate a type of lesion in the shoulder of professional pitchers which I do not think one sees in other individuals of the same age period.

Fig. 8—The exostosis or deposit in the posterior inferior region of the glenoid cannot be identified by the ordinary anterior posterior or posterior anterior view of the shoulder. Our x-ray technician, Mr. W. Ross Mitchell, developed the technic shown here. External rotation of the humerus with tilting of the x-ray tube about 5 degrees is the position which rotates the head of the humerus and the glenoid to a position which throws the thickened area in relief.

Because of the excessive use of the arm and the tremendous pull on the posterior capsule and the triceps tendon, there develops on the posterior inferior border of the glenoid fossa a deposit of bone strikingly similar to the osteoarthritic deposit that one sees in older people. The location of this deposit is such that it produces an irritation of the capsule and of the synovial

Fig. 9—Typical osteochondritis of the elbow. The patient was operated on in 1925 at age of 26, he continued as a professional pitcher until 1940, a period of fifteen years. Roentgenogram taken at age of 41.

membrane. This exostosis or deposit also produces an irritation of the circumflex nerve with referred pain to the deltoid region. The symptoms are local discomfort and sensitiveness in the posterior shoulder plus referred pain to the deltoid. When the player attempts to throw hard after one or two innings, he suffers so much pain

and discomfort that he is unable to continue in the game (figs. 1, 2, 3 and 4).

Careful observation of the position of the arm and the arc of motion helps in the proof of the cause of dis-

Fig. 10—Veteran pitcher aged 28 with osteochondritis and multiple loose bodies in olecranon fossa

ability. On observing a professional pitcher as he "warms up," throwing a ball easily while he gradually increases its speed, one will notice that when he begins to "stretch" he seems to be trying to throw his arm at the catcher. After the "warm up," he reports that his arm is "loose" and feels fine. This statement is true,

Fig. 11—Typical loose body near internal epicondyle of a pitcher aged 23

because to be effective his arm must be relaxed at the finish of the delivery. When the arm is "tight" the muscles are spastic and effectiveness is lost. One does not have to draw on the imagination to appreciate the tremendous pull on the posterior shoulder as the weight of the arm is swished forward in a flail-like motion obliquely across the body. This constant strain tends to cause the development of a pathologic process in the posterior and inferior margin of the glenoid fossa which is strikingly similar to the formation of the

exostosis in the other joints that have been subjected to excessive strain and overuse. Fortunately, this is not a constant disability of the "veteran." I have examined professional pitchers who after twenty years of active baseball life show no such deposits, while on the other hand I have seen youngsters of 20 or 21 years in whom these same changes have already occurred. They may develop gradually with an increase in severity or may have a sudden onset. The pitcher may be able to tell the day and the pitch when he suffered this

Fig. 12—Osteochondritis of the elbow of a pitcher aged 21.

sudden pain in the back of his shoulder. The pain persists and he can throw "hard" only a few innings and then the local posterior pain plus the referred pain to the deltoid becomes so great that his arm feels "dead." It is a common observation that deposits in other joints may exist for a considerable time, causing no inconvenience. For instance, when a sneeze is said

Fig. 13—Osteochondritis of the elbow of a pitcher aged 26, no disability.

to produce an attack of lumbago, the roentgenogram may show deposits which have been years in developing. I do not believe one can say that a sudden strain is responsible for the lesion I am attempting to describe.

The treatment of the exostosis or deposits in this part of the shoulder is difficult, as it is distinctive of the baseball player. It causes no pain or discomfort for normal function of the shoulder, not even in throwing a baseball at moderate speed. Symptoms are produced only when the baseball is thrown hard. Therefore, it

Fig. 14—Osteoarthritis of the elbow of a veteran pitcher

is not a question of having the shoulder perform a normal function but of rehabilitating it to perform again the abnormal function that produced the pathologic process.

If one desires to explore the posterior inferior border of the glenoid at the point of thickening of the margin of the glenoid, it can be done by making a curved incision over the posterior shoulder, detaching the scapular section of the deltoid and retracting it laterally. Then, with safety, one can approach the posterior capsule of the joint by separating the teres minor from the infraspinatus. The infraspinatus muscle protects the infraspinatus nerve, and the retraction of the teres minor carries with it the circumflex nerve. It is now possible to remove the exostosis. My experience has not been sufficient, however, to advocate this operative procedure with the assurance that a baseball pitcher will be able to resume his profession (figs. 5, 6, 7 and 8).

ELBOW LESIONS

The elbow lesions of the professional pitcher fall within the group of so-called osteochondritis and may appear any time during his career. It is not unusual to see loose bodies in the olecranon fossa in youngsters in their late teens who began to pitch for their teams as boys of 12 and 13. Curiously enough, aside from the olecranon fossa and the tip of the coronoid process, these semidetached bodies also appear in the region of the internal epicondyle and cause irritation of the ulnar nerve. Surgical removal does away with all symptoms and restores function so that pitching is possible.

In 1925 I removed a loose body from the olecranon fossa of an athlete who continued as a professional pitcher for fifteen years. The roentgenogram made at

the end of this time (fig. 9) shows what is the typical osteochondritis of the professional pitcher (figs. 10, 11, 12, 13 and 14). A discussion of the etiology and pathology is unnecessary. It is an established fact that trauma of hyaline cartilage produces hypoplasia and the development of loose bodies. As I have stated, this condition is not extremely disabling. A large percentage of the veteran ball players are unable to extend their throwing arm fully, and roentgenograms will disclose that this obstruction is caused by osteophytes or loose bodies. In a large number of cases these loose bodies produce no symptoms.

THE EFFECT OF ALKALI ON CRYSTALLURIA FROM
SULFATHIAZOLE AND SULFADIAZINE

LEON SCHWARTZ, M.D., HARRISON F. FLIPPIN, M.D., JOHN G. REINHOLD, Ph.D., AND ALBERT H. DOWN, M.D., PHILADELPHIA

Recent medical literature contains many reports of hematuria, oliguria, anuria, pain in the loin and uroliths associated with the use of sulfapyridine or sulfathiazole. These renal complications are due, in part if not entirely, to the presence of sulfapyridine or sulfathiazole crystals in the urinary tract. Certain of these toxic effects necessitate discontinuance of chemotherapy at a time when treatment with these drugs is most desired. We have previously¹ stressed the importance of maintaining urinary outputs of at least 1,200 cc. daily in order to facilitate the excretion of these compounds from the body. At this time we wish to present briefly our observations

Crystal Counts in Relation to the Use of Alkali

on the effect of alkali on the incidence and number of crystals detected in the urine of patients receiving sulfathiazole or sulfadiazine.

Aided by a grant from the American Philosophical Society From the Committee for the Control of Pneumonia, Philadelphia General Hospital.
1. Flippin, H. F., Reinhold, J. G., and Schwartz, Leon Sulfapyridine and Sulfathiazole Therapy in Pneumococcal Pneumonia J. A. M. A. 116: 683 (Feb. 22) 1941

While studying the comparative therapeutic effectiveness and toxicity of sulfathiazole and sulfadiazine on pneumonia, special studies were carried out on the urine of 100 adult patients. Of this group 50 received sulfathiazole and 50 sulfadiazine. A total of 290 samples of urine were examined, of which 180 (93 sulfathiazole, 87 sulfadiazine) were from patients who received no alkali and 110 (56 sulfathiazole, 54 sulfadiazine) were from patients to whom sodium bicarbonate was administered in an amount equal to that of the drug. In general, the two groups, as regards both drug and alkali, were comparable.

Samples (15 cc.) of urine passed before breakfast were placed in a test tube and sediment was allowed to separate at room temperature for from four to six hours. A drop of urine, removed by means of a pipet, from the bottom of the test tube was examined under the low power of the microscope and crystal counts were recorded on the basis of the average number of crystals of the drug observed in ten separate fields. All samples of urine were tested with litmus and those giving a neutral reaction were included with those classed as alkaline.

As indicated in the accompanying table, the incidence and number of crystals of the drug found in the urine samples were distinctly less in the group of patients receiving alkali together with either sulfathiazole or sulfadiazine. This difference was statistically highly significant (chi square) in the sulfathiazole-treated group but fell short of significance in the sulfadiazine treated patients. In both groups crystals were found more frequently and in greater numbers in acid urine. Patients receiving sulfadiazine showed fewer crystals in their urine than did the sulfathiazole-treated group. This finding is in keeping with previous observations² on the comparative renal toxicity of these drugs.

Crystal counts made by the Addis technic on centrifuged freshly voided specimens indicated the existence of a similar relationship to administration of alkali and to urine reaction, although the total number of crystals found was smaller.

CONCLUSION

It would seem advisable, in order to decrease the incidence and number of crystals of these drugs in the urine, to administer an alkali with sulfathiazole, and possibly also with sulfadiazine.

2031 Pine Street.

REDUCTION OF GROWTH RATE IN GIGANTISM TREATED WITH TESTOSTERONE PROPIONATE

FRED P. CURRIER, M.D.; CHARLES H. FRANTZ, M.D., AND
RAY VANDER MEER, M.D., GRAND RAPIDS, MICH.

During the past five years several authors have suggested that there exists an antagonistic action between certain hormones and those of the pituitary. More specifically it was suggested by von Drigalski and Diethelm¹ that the male sex hormone acts as a physiologic brake on the growth-producing hormone of the anterior lobe of the pituitary gland. They described the use of testosterone propionate in large doses in a case of hypophysial gigantism with rather uncertain effects of the treatment. It would seem that any decrease in the rate of growth would be due either to a decrease in the amount of growth-producing hormone of the anterior lobe of the pituitary gland or to an earlier closure of the epiphysal line. It was suggested by MacCullagh² that testosterone propionate did not increase the rate of the epiphysal closure beyond normal.

The following is a report on the rate of growth in a case of hypophysial gigantism during treatment with testosterone propionate over a period of two years.

REPORT OF CASE

History.—A boy aged 11 years, was referred to us because of mental retardation and gigantism.

The father, aged 50, is living and well. He is the tallest in the family and measures 5 feet 11½ inches (182 cm.). He has four brothers, and the youngest is 5 feet 4 inches (162 cm.) tall. There has been no history of gigantism on his side of the family.

The mother died at the age of 44 of cancer of the uterus. She was 6 feet 1 inch (185 cm.) tall and weighed 198 pounds (89.8 Kg.) when in good health. Her father was 6 feet 3 inches (190 cm.) tall, and he is still living at the age of 66. A maternal uncle was 6 feet 3 inches tall and a maternal great uncle was 6 feet 5 inches (196 cm.) tall. There has been no history of chorea, migraine, insanity, diabetes or heart disease in the family. The mother had had tuberculosis at the age of 20, with no recurrence.

Growth of Patient With and Without Treatment

Treatment	Increase in Height
Eighty-six days with testosterone propionate.....	¾ inch
One hundred and six days without testosterone propionate....	½ inch
Fifty-six days with testosterone propionate.....	½ inch
Forty-nine days with testosterone propionate.....	0
Two hundred and twenty-five days with testosterone propionate	½ inch

The mother had a difficult labor of twenty-four hours following an early rupture of the membranes and was finally delivered by forceps of the patient, who at birth weighed 7½ pounds (3,403 Gm.) and was 24½ inches (62 cm.) tall. He was a bottle-fed child. There was no history of injury and no unusual childhood diseases. He walked at the age of 13 months but was slow in speech development, talking at 3½ years. Evidence of early gigantism was already present at the age of 2 years. At that time he was 39 inches (99 cm.) tall and weighed 32¾ pounds (14.9 Kg.). When 3 years of age, he was sent into the orthopedic clinic of Blodgett Memorial Hospital with inversion of both feet. He was again seen the next year and referred to the pediatric department, in which the observation of mental retardation was made and the fact was noted also that he was microcephalic, the circumference of his head being 19¾ inches (50 cm.). At the age of 10 he was again seen in the orthopedic clinic, and a note was made that he showed considerable increase in the length of all long bones with accentuation of the previously noted inversion of the feet. Roentgen examination at that time revealed normal osseous structure except for a slight abnormality at the epiphysal line of the right ankle. A roentgenogram of the skull showed a shallow pituitary fossa but no evidence of any other abnormality.

On general examination on Feb. 25, 1939 the boy was seen to be unusually tall—68¼ inches (173 cm.). He weighed 121 pounds (54.9 Kg.). He was microcephalic. The hair of the scalp was thin, and there was no pubic hair. The skin was fair and pale. The eyes showed normal coloring of the scleras; the pupils were round and equal, and they reacted to light and in accommodation. Extraocular movements were normal. The fundi and fields were normal. The ears showed no abnormality, although the hearing was decreased. The boy heard a watch on the left side at 2 inches (5 cm.) and on the right at 5 inches (13 cm.). There was no nasal obstruction and no deviation of the septum. The mouth showed normal teeth with occasional caries. The tongue was normal in size and was without tremors. The throat was slightly injected. The tonsils were present. The lungs were clear to auscultation and percussion. The heart was normal as to size, rhythm and sounds. The blood pressure was 108 systolic and 65 diastolic.

2. Flippin, H. F.; Rose, S. B.; Schwartz, Leon, and Domm, A. H.: Sulfadiazine and Sulfathiazole in the Treatment of Pneumococcal Pneumonia: A Progress Report on Two Hundred Cases, *Am. J. M. Sc.* **201**: 585 (April) 1941.

1. von Drigalski, Wolf, and Diethelm, Lothar: Regressive Skeletveränderungen bei hypophysären Hochwuchs, *Klin. Wchnschr.* **16**: 628-632 (May 1) 1937.

2. MacCullagh, E. P.: Treatment of Testicular Deficiency with Testosterone Propionate, *J. A. M. A.* **112**: 1037-1044 (March 18) 1939.

tolic. The abdomen showed no masses or tenderness. The liver, the spleen and the kidneys were not felt. Rectal examination gave negative results.

Both deep and superficial reflexes were normal. The patient reacted normally to pain, light touch temperature, motion and position and vibration.

Fig. 1.—Patient (in center) at the age of 12 years (on May 5, 1939), 70 $\frac{1}{4}$ inches (178.4 cm.) tall. Normal heights for this age range between 50 and 62 inches (127 and 157 cm.). Our patient exceeds the tallest boy in this group by about 7 inches (18 cm.).

The lower extremities showed decided angulation of the right ankle, knee and hip. The right femur was longer than the left. The right calf was $\frac{3}{4}$ inch (1.9 cm.) less in circumference than the left. The right thigh was externally rotated and abducted.

The blood showed 85 per cent hemoglobin. The erythrocyte count was 4,500,000 and the leukocyte count 6,000, with 72 per cent polymorphonuclear leukocytes, 24 per cent lymphocytes, 1 per cent monocytes and 3 per cent eosinophils. Urinalysis showed the urine to be entirely normal. The dextrose tolerance test showed a normal curve. The level of nonprotein nitrogen in the blood was 30 mg., of phosphorus 4.6 mg. and of calcium 8.8 mg. per hundred cubic centimeters. The Kahn reaction was negative. The basal metabolic rate was 26 per cent.

The diagnosis made was (1) gigantism on the basis of pituitary disturbance and (2) mental retardation.

Treatment and Course.—On March 17, 1939 wedge osteotomy at the junction of the neck and shaft of the right femur was done in an attempt to correct the antifixion and coxa valga. The patient made an uneventful recovery.

Treatment with testosterone propionate was started on March 29, in doses of 5 mg. every four days.

On May 5 the cast was removed, and the patient's height was 70 inches (178 cm.). Therapy with testosterone propionate was continued up to July 29, at which time his height was 70 $\frac{1}{4}$ inches (178.4 cm.).

During the next three and one-half months no testosterone propionate was used, and the patient gained $\frac{1}{2}$ inch (1.3 cm.).

On November 13 the boy fell off a chair and broke his right femur. He was hospitalized; traction was used, and later on a cast was applied to the leg.

On March 9, 1940 the cast was removed and the boy was allowed to walk on crutches. His height was then 72 $\frac{3}{4}$ inches (185 cm.). Treatment with testosterone propionate had been resumed on January 29 and has been continued since then.

On May 4 and on June 21 his height was still 72 $\frac{3}{4}$ inches.

On Feb. 15, 1941 he was 73 $\frac{1}{4}$ inches (186 cm.) tall (fig. 3).

As far as we can determine, the orthopedic operation had no effect on the patient's height; nevertheless we submit the figures in the accompanying table as to the patient's rate of growth when he was not in the cast and was not using any orthopedic appliances. The consecutive periods of treatment began on March 29, 1939.

Statistics on heights³ have shown the average height at birth to be 21 inches (53 cm.) and at 13 years of age 59 $\frac{5}{100}$ inches (150 cm.). Thus the average gain for thirteen years is 2 $\frac{9}{100}$ inches (7.4 cm.) a year. Our patient's height at birth was 24 $\frac{1}{2}$ inches (62 cm.) and at the age of 11 was 68 $\frac{1}{4}$ inches (173 cm.). Thus his average gain per year was 3 $\frac{07}{100}$ inches (10 cm.) as compared with the normal 2 $\frac{90}{100}$ inches (7 cm.). While he was under treatment from the age of 11 $\frac{1}{2}$ years to 13 $\frac{1}{2}$ years his average gain per year was reduced to 2 $\frac{1}{2}$ inches (6 cm.). This is $\frac{42}{100}$ inch (1 cm.) less per year than the rate of growth of a normal child and 14 $\frac{1}{100}$ inches (3.6 cm.) per year less than his previous rate of growth.

Figure 2.

Figure 3.

Fig. 2.—The patient at the age of 12 years shows increased length in all long bones, some degree of microcephalism, prominence of breast tissue, absence of pubic hair but normal development of the testes and the male organ.

Fig. 3.—The patient at the age of 13 years measures 73 $\frac{1}{4}$ inches (186 cm.). There is still considerable prominence of the breast tissue. Pubic hair is present, and the testes and the male sex organ have developed to the size normal for this age. The boy has been treated with testosterone propionate for two years.

CONCLUSION

In a case of hypophysial gigantism treatment with testosterone propionate in small doses apparently had a deterrent action on the rate of growth over a period of two years.

NEUROSURGICAL TREATMENT OF CERTAIN ABNORMAL MENTAL STATES

PANEL DISCUSSION AT CLEVELAND SESSION

EDITORIAL NOTE.—Following is a condensed report of a panel discussion on the neurosurgical treatment of certain abnormal mental states, presented before the Section on Nervous and Mental Diseases at the annual session of the American Medical Association in Cleveland. The technique was relatively new for the presentation of a medical subject. DR. PAUL C. BUCY, Chicago, acted as moderator. The following physicians took part in the discussion:

WALTER FREEMAN, Washington, D. C.
M. A. TARUMIANZ, Farnhurst, Del.
THEODORE CHARLES ERICKSON, Montreal.
J. G. LYERLY, Jacksonville, Fla.
H. D. PALMER, Philadelphia.
ROY R. GRINKER, Chicago.

Following the discussion, opportunity was granted for questions from various members of the group to one another and also from those in attendance on the meeting. The condensed report has been edited in order to avoid duplication and to eliminate confusing statements. The discussion, however, reflects the nature of the method of presentation.

DR. WALTER FREEMAN, Washington, D. C.: Prefrontal lobotomy consists in the surgical interruption of certain tracts in the white matter of the frontal lobes. It has been employed in the treatment of some of the intractable psychoses and neuroses. First reported by Egas Moniz of Lisbon in 1936, the operation was introduced into this country by Freeman and Watts and was later modified by them. It has been employed by them in some 80 cases during the past five years. The best results have been obtained in cases of involutional depression and the obsessive compulsive states.

The technique is, briefly, as follows: The line of the coronal suture is marked out on the scalp, an incision is then made over this suture, and the skull is trephined 5 cm. above the zygoma. When hemostasis has been secured an instrument is introduced into the opening and the white matter is cut in the plane of the coronal suture. This is most important because if the incision is made in front of this plane the desired results are not obtained. If one gets too far back there is too much mental dulling; if one slips down into the middle fossa there is bleeding, and if one gets too near the midline one may catch the anterior cerebral artery.

The result of the operation is marked attenuation of the impact of the psychotic ideas on the patient. The ideas may continue of their own momentum but the affect is bleached. It is as though the patient were no longer interested in the ideas, whether delusional, hallucinatory or obsessive. He loses interest in himself.

I think that these results are obtained because this operation cuts across a band of fibers connecting the thalamus with the frontal lobe. As a result the nucleus medialis dorsalis of the thalamus degenerates. Following the operation the cortex is histologically intact. Its lamination is well preserved. However, there is some atrophy of the frontal pole postoperatively, as I have demonstrated twice by pneumoencephalography.

In the electroencephalogram there are no distinct changes seen between the preoperative and postoperative records. With the intelligence tests that I have used there is no distinct difference between the results before operation and two weeks after operation in some 40 cases. The same holds true for the Rorschach test. Other personality tests administered later on indicate a widening of the horizon of the individual, lack of preoccupation with self, a diminution in the neurotic tendency and a replacement of introversion by extraversion.

Of the 80 patients 20 are regularly employed, 22 are keeping house, 7 are partially employed and only 5 are in institutions. There have been 3 operative deaths in the series, all occurring among the first 30 patients.

I think on the basis of observation of these cases that the frontal lobes are concerned with foresight, that is, with looking into the future, and with the consciousness of the self. The patient loses interest in himself following operation. He is no longer upset by the idea that he has syphilis or that he is being poisoned, spied on and the like. The ideas continue of their own momentum for a while. The mannerisms and compulsions and other motor activities persist even longer.

From the social point of view these patients show the maximum change. As a rule they are a little cheerful, a little outspoken, sometimes rather tactless. They say the first thing that comes into their minds without weighing the question as to what the effect will be on the listener; hence they are sometimes rather undignified, especially in the medium of the family. The reduction in the consciousness of the self applies equally well to the bodily organs. Patients who had been confirmed hypochondriacs no longer are interested in the functioning of their organs. Their lack of concern and their lack of self consciousness is outstanding.

It is good for us to have a little self consciousness, it is good for us to be a little concerned over the future, it is good for us to be able to contemplate and to speculate, because these are some of the highest of human traits; but when concern over the future leads to blocking of all action, when we become self conscious to the extent that we believe we are being poisoned or followed, when we contemplate and speculate way off in the stars some place and lose interest in our dinners and the comic strip; and when thoughts come into consciousness with the intensity of sound, then prefrontal lobotomy may offer something of importance in the handling of these serious neuroses and psychoses.

MODERATOR BUCY: Dr. Freeman, you mentioned various possible complications, such as damage to the anterior cerebral artery, getting down into the temporal fossa or perhaps cutting a little too far posteriorly and producing a vegetative state. How often do such complications occur?

DR. FREEMAN: There have been 2 patients suffering from hemiplegia, 1 of them due to cutting the anterior cerebral artery and the other to getting the lesion too far back in the basal ganglion. There are 5 patients who are necessarily institutionalized, some of them because the operation was inadequate and some because it was too extensive.

MODERATOR BUCY: Do you have any reason, other than the reasons you have stated, for attributing the effect to interruption of afferent pathways from the thalamus to the frontal lobes rather than interruption of pathways connecting the frontal lobes to other parts of the brain?

DR. FREEMAN: I have studied some sections behind the plane of the incision and have found relatively unimportant degenerations in these fibers from the cortex to the more basal portions.

DR. J. G. LYERLY, Jacksonville, Fla.: Dr. Freeman, you stated that with the means of testing that you used there has been no evidence of damage to the patient

TABLE 1.—*Diagnosis and Postoperative Results in Dr. Lyerly's Cases*

Diagnosis	Greatly Im- proved	Moder- ately Im- proved	Slightly Im- proved	Tempo- rarily Im- proved or Failures	Total	Em- ployed
Involuntal melancholia . . .	14	4	4	2	24	13
Manic depressive . . .	2	3	1	2	8	2
Schizophrenia	1	..	1	..
Psychoneurosis with de- pression	2	3	..	.	5	3
Psychopathic personality	—	—	.	1	1	..
Total..	18	10	6	5	39	18
Percentage	46.2 (71.8)	25.6	15.4	12.8		46.2

Seventeen of these patients were operated on at the Florida State Hos- pital at Chattahoochee.

psychologically. Does that mean you think there are other means of determining damage that you have not used?

DR. FREEMAN: Nichols and Hunt devised some special technic, using arithmetical progressions and also Halstead's equivalent and nonequivalent stimuli, and in their case of bifrontal lobectomy they were able to discover defects, although their patient had an intelligence quotient of around 120. I do not say that there are no defects in these persons. My idea, and I think it is shared by others, is that the defect is in the motivation rather than in the equipment. In other words, as Brickner originally stated, the process which enables us to add two and two and find that the result is four is different from the motive that causes us to add two and two and find out the result is four. These patients are satisfied before they reach perfection.

RESULTS IN THIRTY-NINE CASES

DR. LYERLY, Jacksonville, Fla.: In performing this operation I remove a button of bone in the prefrontal region of the skull with a trephine about over the middle of the second frontal convolution, halfway between the tip of the frontal lobe and the Rolandic area. A short incision is made in the cortex at this point and a lighted brain speculum is inserted. Then by blunt dissection transverse cuts are made through the white matter. I try not to go through the cortex at any other point so as not to injure any vessels or get any bleeding. The incision is made just anterior to the anterior horn of the lateral ventricle. Since doing this operation first in 1937 there have been 39 cases up to 1941. Most of the patients were operated on two or more years ago; 11 in 1937, 15 in 1938, 8 in 1939 and 5 in 1940. There were 17 men and 22 women. The average age of the patients was 49 years, varying from 26 to 78 years. The majority, 24, suffered from involuntal melancholia. The average duration of the symptoms was forty and six-tenths months, ranging from three months to twenty-seven years. The average gain in weight after operation was 30½ pounds (14 Kg.). The greatest

gain in weight in one case was 97 pounds (44 Kg.). That patient doubled her weight. She weighed only about 90 pounds (41 Kg.) before operation.

In classifying these cases the diagnosis was made by one or more psychiatrists in addition to myself, and frequently the services of a psychologist were used in making psychometric tests before and after operation. I have grouped these cases into greatly improved, moderately improved, slightly improved and temporarily improved. By "greatly improved" I mean the patients were restored to practically normal individuals, were able to be discharged from the hospital and became socially adjusted and returned to work. By "moderately improved" I mean that the patients became socially adjusted individuals and were discharged from the hospital but for various reasons they did not go back to work. Some of these patients were on insurance. By "slightly improved" I mean that the patients could not be discharged from the hospital, but their depression and mental suffering were greatly relieved and they were no longer such a problem in the hospital. They no longer required tube feeding. By "temporarily improved" or "failures" I mean the ones that improved only temporarily and later relapsed or in some cases went from a depressed state to a manic or hypomanic state. The "greatly improved" formed 46.2 per cent, and 25.6 per cent were "moderately improved." Thus in 71.8 per cent of the cases the operation produced definitely beneficial effects. The slightly improved formed 15.4 per cent, and the temporarily improved or failures 12.8 per cent.

In table 2 I have correlated the duration of the symptoms and the postoperative gain in weight with the degree of improvement. The patients who made the best improvement are the ones who had the shorter duration of symptoms and the ones who had the largest gain in weight after the operation.

DR. ROY GRINKER, Chicago: I must confess that I do not understand the correlations indicated. I do not see a great deal of difference in the average duration of symptoms of the "greatly improved" and the "slightly improved." Gain in weight is merely evidence of improvement in the psychosis and, no matter what you do, when the psychosis is improved the patient gains weight, so I do not see the significance of the correlation.

TABLE 2.—*Correlation of Postoperative Results with Average Preoperative Duration of Symptoms and Average Postoperative Gain in Weight in Dr. Lyerly's Thirty-Nine Cases*

	Greatly Improved	Moder- ately Improved	Slightly Improved	Temporarily Improved or Failures
Duration of symptoms. . .	14.6 mos.	53.2 mos	15.3 mos.	21 mos.
Gain in weight	38.3 lbs.	32.1 lbs.	12 lbs.	—5 lbs.

DR. LYERLY: These average figures do not represent the actual picture. In the majority of cases the shorter the duration of symptoms, the greater the improvement.

DR. GRINKER: It also appears to me that in some instances the duration of the disease prior to operation has been very short.

DR. FREEMAN: I have been accused of that too.

DR. LYERLY: No, I would not say that. I have adopted the plan that the psychiatrist turns the patient

over to me for operation when he thinks that is the best procedure to use or that other methods have failed. Many of the patients have had either insulin or metrazol shock therapy. In some of the cases the psychiatrist thought that shock therapy was not indicated or would be too dangerous and that the operation would be the less severe procedure.

DR. GRINKER: I note that one patient had been ill for only four months, another for six months and another for seven months. It seems to me that these are exceptionally short periods to test out other methods of therapy.

DR. LYERLY: I agree that four months was a rather short time but that was one of the early cases. I do not think we would operate on a patient that early now. That was in 1937 or 1938, and at that time we did not know exactly what was the best procedure to follow.

DR. FREEMAN: Dr. Lyerly, what do you mean by "improvement"? Does that take in only the subjective complaints of the patient or is it also the opinion of the family? Have you had any patients who are not improved or are real problems because of their destructive, irrational behavior following operation?

DR. LYERLY: By "improvement" I mean that the patients came out of the severe mentally depressed states and became happy, cheerful and slightly elevated. A few of the patients became too elated and had to be institutionalized. These I put in the failure group. Some of them were inclined to spend money that they did not have and for that reason I think they were not improved to the point that would be most pleasing to the family.

Probably the reason some of these patients developed too much of the elevated type of personality was that too much of the prefrontal lobe was disconnected from the rest of the brain. For that reason I have done some of the operations bilaterally but more anteriorly. In 4 cases I have done the operation only on one side with very good results and with a good gain in weight after the operation, but usually such an operation is not extensive enough.

DR. M. A. TARUMIANZ, Farnhurst, Del.: How soon after operation did you notice some improvement?

DR. LYERLY: Immediately after the operation. The patient frequently wakes up with a smile on his face or is happy and more elated, more relaxed. However, during the first few days or weeks he is in a confused state, with considerable impairment of memory and disorientation.

DR. TARUMIANZ: Is it your experience that forty-eight or seventy-two hours after the operation they show definite delusions of the former nature?

DR. LYERLY: Occasionally they may have a few of the old symptoms, but as a rule they do not. During the confused period they are usually more or less incontinent. They lie listlessly in bed. Sometimes they are inclined to pull the bedding off the bed or to get up and wander around the room. They frequently have to be restrained. They forget that they have been operated on. But within a week the memory returns and they do not recall anything that happened during that confused period. Their own usual type of personality then returns and persists. They usually are out of bed in about two weeks and frequently out of the hospital shortly thereafter.

DR. H. D. PALMER, Philadelphia: Were all of the 24 patients with involuntional melancholia subjected either to metrazol or to electric shock therapy and had such therapies failed before this operation was attempted? I note a 60 per cent recovery rate in your involuntional melancholia group following operation, whereas with metrazol therapy one can anticipate about a 73 per cent recovery rate in these cases and with electric shock about an 85 per cent recovery rate.

DR. LYERLY: Most of them have had either insulin or metrazol before operation, but not all. One patient had been in the hospital with a severe depression for over four years. The operation resulted in only a slight improvement. I think her severe symptoms had been of too long duration and I probably wouldn't operate on her today.

DR. TARUMIANZ: I don't agree with you, Dr. Lyerly, about duration. I have had cases of twelve years' duration and still the patients recovered after operation and went home.

DR. LYERLY: One patient was a rather old man with a severe agitated depression. All he would say was "Send me to the electric chair and get it over with." He was in constant motion.

DR. FREEMAN: His condition was too bad for shock therapy?

DR. LYERLY: I thought it was and regarded the operation as a less severe procedure. Following the operation he could have been discharged from the hospital, but he hasn't any home. He gained 91 pounds (41 Kg.).

DR. FREEMAN: My record is 130 pounds (59 Kg.) gained.

MODERATOR BUCY: Dr. Grinker, I should like to ask if you feel that these large gains in weight, such as 90 pounds and 130 pounds, can be attributed entirely to improvement in mental symptoms or are they possibly on a physiologic basis quite apart from the mental symptoms?

DR. GRINKER: I think there is a very strong possibility that those excessive gains in weight are due to some disturbance in the cerebral centers. Particularly one might imagine traction on the hypothalamus or bleeding in the neighborhood. It is the moderate gain in weight that is so characteristic of improvement in the anxiety states to which I had reference.

DR. FREEMAN: I had one experience in which the anterior cerebral artery was injured, resulting in softening on the mesial aspect of the left hemisphere. The patient ate very eagerly. In a period of four hours she consumed 4,600 calories and three quarters of a pound of chocolate candy before she vomited—and was immediately ready for more. I think that is definitely a type of morbid hunger such as is found in some cases of frontal lobe disease. However, in most instances I believe that these patients get so much more pleasure out of their bodies, out of the matter of eating, out of the process of bathing, and enjoyment in other fields too, that the gain in weight is merely an expression of their contentment with existence as it is. The girl who gained 130 pounds after operation had lost nearly 100 pounds beforehand. She had starved herself through the delusion that the food was being poisoned.

DR. LYERLY: One woman aged 59 had suffered from a severe depression for over a year and been treated

in various places before being committed to the state hospital. Following the operation she made a good recovery. Her husband had a stroke and became paralyzed on one side about two years after the operation. Since then she has gone to work and earned their living. She gained 36 pounds (16 Kg.).

One man had a severe traumatic neurosis, suffered from headaches and was addicted to alcohol. He said he drank because he was worried, depressed and afraid all the time. After the operation his headaches disappeared. He has not drunk any since the operation. He says he does not worry and therefore sees no need for drinking. This man has been working regularly since the operation. Before the operation he was out of work half the time.

DR. FREEMAN: I operated on 2 alcoholic addicts and they both got drunk before they left the hospital.

DR. LYERLY: I have done forty-four operations in all and there have been no deaths from the operation, there have been no complications such as paralysis, no aphasia, nor other signs of organic brain damage that could be demonstrated except for these mental changes. Three patients each had a slight convulsion after operation. One had a convulsion during a period of influenza with a temperature of 103 F. Another had a slight convulsion in a hypomanic rage. And another patient had a slight convulsion without any known cause.

EIGHT CASES OF INVOLUTIONAL MELANCHOLIA AND TWO OF SCHIZOPHRENIA

DR. TARUMIANZ: About three and one-half years ago Dr. Francis Grant and I decided to present this particular type of more drastic approach to our board and obtain its sanction to proceed with such operations in a state hospital in Delaware. Thus we selected, with the help of Dr. Freeman, 10 cases. Eight of them were of the involutional melancholia type, and 2 of them were of the schizophrenia type with involutional changes. These patients had all been in the hospital for two or more years and some were psychotic for some time before being committed to the hospital. The youngest was 37 years of age, the oldest 66. They were all women with 1 exception. They were all much deteriorated. Most of them were at times extremely agitated and deeply depressed. Seven of the 10 had suicidal tendencies. Two of them had attempted to commit suicide on many occasions. One was quite emaciated because of her unwillingness to take nourishment. Of the 10, 2 have died. One died from post-operative hemorrhage four days after the operation. One died two years after the operation from cerebral hemorrhage. Seven returned home a few months after operation and became fully adjusted, with slight euphoria and very slight unreasonableness, perhaps due to lack of inhibition. One, not having a home, is still in the hospital doing very well. Of these 10 patients, 7 have become fully adjusted socially and mentally and 2 are working in their offices as they did before their illness. With such results one cannot help but consider prefrontal lobotomy as an adequate type of approach in chronic cases after all other types of conservative as well as semidrastring methods have been tried. However, I believe that metrazol treatment is more drastic than prefrontal lobotomy, even though I have never seen a death from metrazol in our hospital and we have seen one case of postoperative death from lobotomy.

From an economic point of view I should like to give some figures as to what this may mean to the public. We have come to the following conclusion with regard to our own cases: In our hospital there are 1,250 cases and of these about 180 would be suitable for such an operation. In our hospital these patients could be operated on for \$250 per case. That will constitute a sum of \$45,000 for 180 patients. Of these we will consider that 10 per cent, or 18, will die, and a minimum of 50 per cent of the remaining, or 81 patients, will become well enough to go home or to be discharged. The remaining 81 will be much better and more easily cared for in the hospital. Thus the hospital will be relieved of the care of 99 patients. That will mean a saving of \$351,000 in a period of ten years. I believe that, these figures being for the small state of Delaware, you can visualize what this could mean in larger states and in the country as a whole.

MODERATOR BUCY: Dr. Tarumianz, in the light of Dr. Lyerly's experience, don't you think it more than likely that your figure of a 10 per cent mortality is unduly high?

DR. TARUMIANZ: I fully agree with you and possibly in the next 25 we might not have a single death. However, we are taking the worst situation that might occur. So far I have not seen a single case that has not responded favorably except those in which death occurred. Two days before I left the hospital I saw 5 of the 7 who are at home and they are still well after three, two, and one and one-half years. About ten days ago Dr. Grant operated on 2 patients with schizophrenia. This is the first time that we have operated on dilapidated schizophrenic patients with long hospital duration after all the shock therapy failed to accomplish anything. One had been quite a problem in the hospital because of her very disturbed condition and her impulsive violence, at times even trying to commit homicide. About forty-eight hours after the operation this woman requested newspapers and magazines. The other 1, who had been mute during nine years of hospital residence, having a catatonic type of schizophrenia, requested a beautician to come and give her a manicure.

MODERATOR BUCY: Recently I have seen some patients diagnosed as suffering from dementia precox, individuals who were particularly agitated and difficult to handle, who were very filthy in their behavior and on whom this operation or some modification of it was performed. They have been transformed into much quieter, almost vegetative individuals. They are much cleaner; they are much easier to take care of. Have you had any experience with such cases and do you believe that the procedure in such a situation would be justified?

DR. TARUMIANZ: I am not ready to answer your question because we took these 2 cases of schizophrenia just ten days ago and have hardly had sufficient time to answer your question.

DR. FREEMAN: I think I can answer that question to some extent. The schizophrenic patients after operation look like patients with dementia precox and talk like them but they do not feel like them. They are no longer particularly interested in themselves and their hallucinations or delusions. The behavior of these patients often shows no particular change for some little time. There are three stages in the recovery: first,

the bleaching of the affect; second, the disappearance of ideas, hallucinations, delusions and so on, and finally the clearing up of motor manifestations.

DR. GRINKER: I wonder if we should worry too much about the economic costs and figures, for these patients are returned home and the cost is now borne by another agency, namely the home rather than the state, which in the long run makes very little difference.

DR. TARUMIANZ: I do not agree with Dr. Grinker, because those patients who have returned home have not become a burden to their families. The women have assumed the responsibilities of their housekeeping, while before the families had to hire housekeepers. Two of them have obtained their former jobs.

DR. GRINKER: I have a second question which I should like to ask Dr. Tarumianz. The amount of attention and interest in the long hospitalized, dilapidated schizophrenic patient is practically nil. Now you have a new operation and you are enthusiastic about it. You bring your patient into the hospital ward. You operate on him. You supply him with nurses. You pay a lot of attention to him. You have brought to bear on this patient a tremendous amount of psychologic care which he did not have before and you get some results. I should like to know how you can determine that it isn't the effect of your new psychologic interest in this patient and not the operation you perform.

DR. TARUMIANZ: We had that on our minds and our first patient had a private graduate nurse at all times prior to operation. She was taken to the occupational therapy department by her private nurse and she was taken to the library; yet she showed no signs of interest because of her agitation, depression and suicidal tendencies. I doubt very much that you are right in saying that we are going to show such a vast change in our treatment of patients who have had lobotomy. As a matter of fact, we do not have any time in which to give such treatment, as improvement occurs in twenty-four or forty-eight hours.

DR. FREEMAN: Also aren't your patients previously treated rather intensively, say, with either metrazol or insulin?

DR. TARUMIANZ: They have all been given all available treatment.

DR. FREEMAN: We have tested out the effect of both operative shock and suggestion in the recovery of these patients. Some patients have been operated on in two stages. The first operation has been done under local anesthesia with all of the ritual of the operating room, the caps, masks and gowns, the drilling of the skull and the operation itself but without relief. Yet the second operation on the other side has given relief.

REPORT OF FIVE CASES OF SCHIZOPHRENIA

DR. PALMER: In the use of the operation of frontal lobotomy at the Pennsylvania Hospital, we have preferred to work in the field of the hopelessly deteriorated patients who have failed to respond to every treatment over a period of years. Seventy per cent of all schizophrenic patients fail to respond to any method of treatment, whereas, as I said in commenting on Dr. Lyerly's material, the involuntal melancholias show 70 to 73 per cent recovery with the metrazol treatment and about 85 per cent with electric shock treatment; therefore, in choosing this chronic schizophrenic group for study we were taking the most unlikely group. Dr.

Edward A. Strecker, Dr. Francis C. Grant and I reported a study of frontal lobotomy in five cases of deteriorated schizophrenia before the American Psychiatric Association in May of this year and the material I should like to discuss here is an abbreviated form of that presentation.

There are 5 cases in our group, 4 women, 2 single, 1 divorced and 1 married, and 1 single man. The range in age is from 25 to 39 years. The shortest preoperative duration of psychosis was five years and the average was more than ten years. The briefest postoperative observation period was one year and the longest two and one-half years. The psychotic patterns were basically schizophrenic, but the group was distinguished by the fact that the psychotic life was not on a negative, passive level but tended to be strikingly violent, disturbed by vivid hallucinations, motivating apprehension, fear, anxiety, suicidal attempts, attempts at self mutilation, destructiveness, aggressive acts, homicidal attacks and assaultiveness of tremendous violence.

Partly in answer to Dr. Bucy's question about the application of this operation to the hopelessly schizophrenic, and partly to present the favorable results in what Dr. Freeman calls "the forgotten patient in the back wards," I would like to give the details of these cases. I also will bring out, in answer to the question raised by Dr. Grinker, the fact that these patients were not neglected before operation but were subjected to all kinds of helpful treatment, both psychologic and physical, over a period of many years.

The first patient was a woman aged 39, a divorcee, ill with schizophrenia for twelve years before operation, who had been under our observation for seven years. The postoperative period has been twenty-two months. The psychosis was characterized by excitability and impulsive violence, several suicidal attempts, refusal to eat, and very distressing auditory and tactile hallucinations. In fact, her distress was so great that she begged that both auditory nerves be cut to eliminate the abusing voices and that a mutilating sexual operation be done to remove the distress of tactile hallucinations involving the sex organs. Deterioration was obvious in that she had apparently had no intellectual life during the last seven years, whereas prior to the onset of her illness she had graduated from college, had a real interest in literature and was adept at languages.

She was given narcosis treatment in 1937 and failed to respond. Following that she was given insulin therapy, having fifty-one treatments with forty-two comas. There was a slight temporary improvement, but she relapsed so severely that insulin therapy was repeated after nine months. This time she was given forty insulin injections with twenty-three comas. No improvement followed this treatment. After seven months she was given eighteen metrazol convulsions and three azoman (3-ethyl-4-cyclohexyl-1,2,4-triazol) convulsions; no benefits were derived from these methods. Frontal lobotomy was performed by Dr. Francis C. Grant on June 20, 1939. The immediate result of the operation was a serene mental attitude with rather a remarkable talkativeness. After three months she was allowed to go home with a nurse, and since that time she has been living in a relatively satisfactory social adjustment, without the nurse, at home. She goes to the opera and the theater, rides horseback, has resumed her interest in languages and in literature and has learned painting and sculpture since the operation.

There is, however, a somewhat vague forgetfulness regarding unimportant things. She has a mildly distorted sense of time relationships. Her naive attitude toward temporal orientation is illustrated by the fact that although she has been sick for longer than thirteen years she believes that she has been ill for a year and is disturbed somewhat by the fact that she has been out of circulation for "twelve whole months."

She states that the operation was unnecessary because her illness was very mild; that doctors always make a great fuss about things anyway and they operated on her without justifiable cause. She has gained 40 pounds (18 Kg.). A severe hypotension, which existed prepsychotically as well as during the course of the psychosis, has been improved to the point where the blood pressure is now approximately normal. She at times shows a little tendency to make ridiculous jokes and to see the funny side of things in a slightly distorted fashion.

The second schizophrenic patient was a woman aged 26 who had been psychotic for twelve years before operation and had been observed by us for five years before operation. She has been seen for fifteen months postoperatively. Prolonged endocrine therapy, narcosis treatment and insulin therapy with forty or more periods of coma had brought about no improvement. The psychosis was characterized by enormous fear of kidnapping, violent assault, and so on. She became so alarmed that she set the house on fire on occasions, preferring to die in the blazing building than to be kidnapped and tortured. She attempted to jump out of windows. On occasion she smashed all the furniture in the house, attacked nurses with tremendous violence and was restrained with great difficulty.

Frontal lobotomy was performed by Dr. Grant in November 1939. The immediate results were very encouraging. The patient was talkative, pleasant, affable, cooperative in an extreme degree. Her appetite, which had been almost nil before the operation—in fact she had required artificial feeding—suddenly became exaggerated, and in the first six months postoperatively she gained 49 pounds (22 Kg.). She read books with her nurse, worked at arts and crafts, and manifested interest in her environment, going for rides and walks and enjoying relatively simple things. It was not felt that she approached her prepsychotic level of intellectual interest. An attack of very virulent pneumonia resulted in death eighteen months after the operation.

The third patient, a single man of 35 who had been under the observation of psychiatrists at the Pennsylvania Hospital for six years prior to operation and for one year after operation, had catatonic schizophrenia. His behavior was of the same assaultive, violent, impulsive, homicidal character. He attempted to mutilate himself. He burned his skin frequently with cigarettes, beat his head against the wall, was incontinent and untidy.

Narcosis followed by typhoid vaccine, insulin treatment and sixteen metrazol convulsions all failed to bring about anything but a transient improvement. Operation April 25, 1940 by Dr. Grant produced a high degree of affability and cooperativeness, complete freedom from violent outbursts, and freedom from the aggressive assaultive attacks. The patient began to renew his interest in card games and checkers and in occupational therapy. During this postoperative year, however, he has remained on a relatively simple level.

Although he goes home occasionally to have dinner with his family he is passive, extremely suggestible and accepts with entirely uncritical attitude the hospital management.

The fourth patient was a woman of 32 under observation because of her psychosis for thirteen years prior to operation and for fifteen months after operation. The onset of the illness was typical, with withdrawal and quiet preoccupation. Gradually there appeared hallucinations, which increased in acuteness and in their distressing nature until she became assaultive, violent, destructive and on one occasion attempted suicide by jumping out of the window. The restlessness was so intense that exhaustion seemed inevitable, and she was several times given narcosis as a means of controlling the agitation and excitement. In 1937 she was given insulin therapy and had forty-six treatments with thirty-four comas. She gained a great deal of weight during this treatment but showed no mental improvement whatever. She was given a second course of insulin therapy seven months later with no improvement.

She was operated on by Dr. Grant, Jan. 15, 1940. The immediate postoperative results were not very encouraging. She remained quiet, entirely passive, very suggestible. Her interest could be aroused for temporary periods, but she quickly lapsed back into what appeared to be preoccupation with fantasies and possibly with hallucinations. However, in the fifteen months since operation she has made very striking improvement. She has gained 45 pounds (20 Kg.), has lost her fatigability, seems more energized. She now goes swimming, bicycling, horseback riding, does very skilful weaving and knitting, and has taken up sculpture and painting, at which she was very competent in her prepsychotic life. She apparently has lost none of the skill which seemed to have disappeared entirely through schizophrenic deterioration. She has learned new games and has taught them to others. There are still, however, periods of preoccupation. She does not resent the intrusion of the doctor in the fantasy life, quickly comes back to reality and appears to have insight into the fact that she is drifting off into fantasy and that is not wholesome. The time sense of this patient is peculiarly distorted. She, like patient 2, is astonished to learn that she has been sick longer than a few weeks. In talking with the nurse she said that she might have been ill for one year. Actually it is more than fourteen years. She is interested in what has happened to her friends, how many of them have married and what they are all doing.

The anticipation of simple things is quite interesting. She wants an ice cream cone or she wants to go for a walk. She wants a dog. She wants to go riding in the car. The intellectual level seems relatively simple as far as her own initiation of interest is concerned, and yet when she is involved in a discussion of more adult things she is normally intellectual.

The fifth patient was a woman aged 25 who was under psychiatric observation for five years before the operation and for two and one-half years after the operation. There was a long history of educational and social maladjustments, years of moral laxness, rudeness, resentment, suspiciousness, obstinacy and irritability before the psychosis. Shortly after the onset of the psychotic phase she became paranoid and had ideas of reference, delusions and auditory hallucinations. There were episodes of violence and destructiveness. She attempted to commit suicide by setting fire to her clothing and by cutting her wrists.

Narcosis treatment of ten days' duration produced no improvement. Insulin therapy was given. She had fifty-one comas, but there was no benefit. Because of the tremendous difficulty in management, the increasing excitability and the destructiveness, frontal lobotomy was performed by Dr. Grant, Oct. 14, 1938. In the immediate postoperative phase this patient also showed little improvement. Gradually over a period of two and one-half years the improvement has become very substantial. She obtained a position one year after the operation as a hostess in a resort and functioned very satisfactorily. She learned to play golf and was able to enter into highly competitive golf games and come off reasonably well from the score standpoint.

One year ago she was married and since that time has gone through a normal pregnancy and delivery. She seems to have retained all of her intellectual capacity, and the comparison of psychometric tests before and after operation shows no change except that the Rorschach test shows a more normal response after the operation.

Summary of Results.—The 1 man improved only to the extent of being less violent and destructive. He has become a more conforming hospitalized, semi-convalescent patient. How much further the improvement will go it is impossible to say, because this is only at the end of one year. The gain of the 3 remaining patients still alive has been very considerable. Only 1 remains in a small private sanatorium in the country where she has horses and her own car and leads a relatively quiet country life, far removed from strict institutional life. One patient is able to live at home without a nurse and appears to her friends to have recovered entirely. The patient who is married seems to have made the best adjustment and perhaps we should call her recovered.

In our opinion at least one year should elapse after the operation before one attempts to judge the degree of improvement. With 3 of the patients there is a restored capacity to anticipate the future, to visualize it usually pleasurably, as in the matter, however, of relatively simple things, trips, cruises, rides, the acquisition of possessions, and so on. It is likely that auditory hallucinations continue in 3 cases, but there is less preoccupation and a rather remarkable ready distractibility, with evidence of insight. With 4 of the patients, and very striking with 2, there is a reclamation of former life material which permits some measure of reorientation with life and with family and friends.

In 3 introversion has been replaced to a striking degree of extraverted activity. There is a highly qualitative and almost wishfully selective distortion of time sense, and we would question whether that is psychogenic in part or whether it is all organically determined.

There are certain qualitative personality alterations which determine better social adaptability. For instance, with 2 patients a former disregard for others, selfishness and egocentricity have been replaced by generosity, thoughtfulness, kindness and consideration. Prepsychotic artistic capacities and an inclination toward intellectual interests, skill in games, both athletic and nonathletic, have been strikingly reclaimed.

From these studies and the studies described by others on this panel there seems to be a gradual shaping up of conclusions regarding frontal lobe functions. The

loss of the self critical faculty, impairment of temporal orientation and curious interference with temporal perspective are most conspicuous in our cases. The mental complacency, self satisfaction, the release of energy which is expended in more extroverted activity, the reduction in social propriety—all these may indicate a more primitive, more simple level of adjustment.

The tremendous gain in weight has been of particular interest because the distribution of adiposity resembles that of pituitary dystrophy; also the abnormal appetite, which at times becomes a desperate hunger, resembles the clinical picture of hyperinsulinism. The possibility of interference by the operation with certain hypophyseal connections, either directly or indirectly through the thalamus, must be considered. It is suggested that indications for the operation of frontal lobotomy be considered in relation to constellations of symptoms, that is, agitation, destructiveness, overactivity, restlessness and mental distress rather than in relation to any diagnostic label. A certain segment of the schizophrenic problem which proved to be impregnable to all other attempts at therapy might furnish good material for further study of this method.

THIRTY CASES OF FRONTAL LOBECTOMY

DR. THEODORE CHARLES ERICKSON, Montreal: I have been asked to discuss this problem in the light of my experiences with frontal lobectomy. In removals restricted to the prefrontal areas I have not observed any changes of course in the reflex activity, in the motor or the sensory system. I have, however, observed all the classic signs of frontal lobe disease, such as euphoria, tactlessness, inappropriate facetiousness and lack of self consciousness. Equally impressive, however, are those patients with complete frontal lobectomy who are indistinguishable from some apparently normal persons. The loss of one frontal lobe is compatible with a very superior intelligence as measured by the Stanford-Binet test, a relatively normal personality as measured by the Rorschach test, and even in 1 of our patients with satisfactory accomplishment in university and scientific school work.

What do these facts mean? They indicate that adequate tests of frontal lobe function are not yet in common clinical usage, although an impetus in this direction has been given by the work of Goldstein and others. On the other hand, the fact that some patients with absence of the frontal lobes cannot be distinguished from normal persons by the usual psychometric tests might almost make one assume that there are many so-called normal persons who do not employ their frontal lobes in everyday life. When one considers the difficulty encountered in demonstrating their function, one is not surprised that the frontal lobes have been called "biologic luxuries" and that an eminent evolutionist has spoken of them as parasitic growths.

A review of 30-odd cases of frontal lobectomy from the Montreal Neurological Institute has impressed me with the variety of intellectual accomplishments and with the diversity of personality changes which these patients may show. One scientific student, of very superior ability, from whom the left frontal, dominant lobe was completely removed back to the ventricle, four years after the operation had a perfect score on the Stanford-Binet with an intelligence quotient of 152, while other patients have had intelligence quotients somewhat below normal.

The personality picture as reflected in the Rorschach test has also shown a considerable variation notwithstanding the remarkable uniformity of personality limitation which characterizes the patient with extensive cerebral damage. There is the patient, for example, reported by Penfield and Hebb and by Harrower-Erickson who had a removal of both frontal lobes. Before operation he presented a behavior problem, irresponsible and childish stubborn. Fifteen months after operation the Rorschach test was essentially normal and his family considered that he was 100 per cent improved. He passed as a normal member of his community.

DR. FREEMAN: Was he able to work?

DR. ERICKSON: He was doing light work around the village.

DR. FREEMAN: I mean employed. Has any patient with bifrontal lobectomy been employed? I have looked up about 8 patients, and none of them, as far as I know, have been able to secure employment.

DR. ERICKSON: I don't think this man has either. None of ours have as far as I know specifically. Some patients with unilateral frontal lobe removal exhibit a perfectly normal personality, while others have given evidence of anxiety, tension and maladjustment. It is evident that a large removal from one frontal lobe does not prevent the development of anxiety states in the presence of distressful situations. I should like to mention certain psychotic states which are associated with focal epileptogenic lesions, particularly in the posterior portion of the frontal region. One of these cases was reported by Slight and Cone in 1937. Following a head injury there were focal attacks beginning in the left side of the mouth. The attacks later became generalized. Following status epilepticus the patient was admitted to the hospital in a confused state with alternate spells of laughing and crying. He was suspicious and he thought he was being persecuted. He talked in response to voices, one of which was his dead mother's, and he had some retrograde amnesia. The mental change was similar in form to that of cases commonly diagnosed as schizophrenia. A right osteoplastic craniotomy was performed and two superficial meningo-cerebral scars were exposed. One cerebral scar was anterior to the motor gyrus where the face movements are represented. There was also another scar just posterior to the rolandic gyri. Both were excised, and subsequent to operation the patient's mental state has been normal and he has been free from seizures for more than six years. He is married and is earning a living. Similar psychotic states secondary to epileptic discharge, arising from the presence of small tumors or scars in the posterior frontal region, have been observed in 6 other cases.

MODERATOR BUCY: Is it safe to assume that the psychotic symptoms disappeared because the scar was removed rather than because part of the frontal lobe was destroyed in removing the scar or because the convulsions were abolished?

DR. ERICKSON: No, I do not think it is, though these psychotic states are quite different from the confused, stupid state of automatism commonly seen after severe epileptic seizures. It is possible that these states are due to a general cerebral disorder as a result of the severe epileptic seizures.

RATIONAL BASIS OF TREATMENT

DR. GRINKER: On both sides of this question there is obviously a great deal of preconception and emotional bias. I think that those who have taken up this procedure have been interested in physical therapy in psychiatry, which has been based largely on a partially expressed and somewhat unexpressed feeling that the psychoses have a definite organic basis. On the other hand, those who are opposed to the method have again an emotional attitude toward a mutilating operation that destroys brain tissue. As long as we realize that on both sides there is some bias, perhaps listeners may conclude for themselves which is fact and which is bias.

In the first place, one tries to find out what type of case is selected for this operation. The statement is categorically made that those cases that are untreatable by conservative methods are selected, and the question that naturally enters my mind is What are those conservative methods? Surely, by conservative methods one does not mean metrazol or electric shock.

We are dealing with a large number of patients who have been chosen from state hospital populations. There have been some private cases, it is true, but when one thinks of what conservative treatment means, of what actual, thoroughgoing psychologic study and treatment mean, it is difficult to imagine that the patients who come from state hospital populations are getting the benefit of that type of treatment.

Again I want to call attention to the short duration of the patients' illnesses, because in looking over the data I have previously expressed my surprise that patients have been operated on after only a few months of mental illness. It is obvious that even the natural process of recovery has not been allowed to take its effect.

In looking over the diagnoses of the cases that have been selected, one finds that operations have been performed on patients with psychoneurosis, manic-depressive psychoses, schizophrenic personality, and so on. It is obvious then that this operation is devised for almost the whole field of psychiatry; yet one very good sign is Dr. Freeman's and Dr. Palmer's insistence that we discuss this matter not from the point of view of diagnosis but from the main presenting symptom, which is anxiety or apprehension, and, as you know, anxiety is not limited to any one neurotic or psychotic condition. As a matter of fact, it is present in all; therefore indication for operation becomes a question of the degree of anxiety.

Another statement that is made is that these people should not be young, and yet in the statistics of cases presented we see patients operated on at the age of 30, 33, 35, and I trust these are still young people. In other words, the anxiety states are not limited to those with so-called involutional melancholia.

Without drawing any conclusion about this difficulty of obtaining proper data, may I discuss first the type of defect after the operation. I think all the members of the panel are agreed that there is some defect, and that a great deal of difficulty has been found in testing the defect. The defect cannot be easily tested by the ordinary formal tests of intelligence. Halstead has shown clearly that persons with high Binet and normal Rorschach tests may show disturbances in categorical behavior that indicate a very severe disturbance even in those who appear well adjusted in their previous environment. There must be developed a technique of

measuring very carefully both the existing function and the defect in the individual before and after the operation.

The question of defect of function of the frontal lobes has been dealt with largely by generalizations. We have heard about defects of association or of synthesis. We have heard about the disturbances of category behavior at the level of abstraction, but we see that such things as initiative, ambition, productivity, creativeness are not measured and sometimes hardly mentioned in the post-operative defect. It seems that what is most likely to confuse the issue is a spurious kind of normality, a kind of normality that may permit the patient to return to situations of responsibility, with disastrous results.

There is another question which cannot be answered here, and that is the result of late scarring. These people have had trauma not only to brain tissue but to blood vessels, and the scarring that results, whether of glial or of connective tissue, will take time to produce its effect. There are now beginning to appear reports of the late development of convulsions following metrazol, insulin and electric shock therapy. It is possible that similar convulsions may appear later following frontal lobotomy.

To explain the improvements, if one may call the total picture improved, is tempting. It was tempting in the problem of insulin therapy when one thought that insulin therapy was the great panacea for schizophrenia, but now that the percentage of remissions is steadily declining to the spontaneous rate one is a little abashed at having attempted explanations. I do not believe that the effect of this operation is purely psychologic. The effect, if it were psychologic, could not last, since any effect on the psychotic individual would soon be overcome by the process of further living.

The second possibility is some general catastrophic reaction, some biologic reorganization which had nothing to do with the actual location of the operation. That has been amply disproved particularly by Dr. Freeman, who has pointed out that the effect is dependent on the quantity and the localization of the tissue cut.

The third possibility is the one that I think all have been agreed on, namely that there are some functions in which the prefrontal lobes are concerned that have to do with the development of anxiety.

I think that we are confronted in considering prefrontal lobotomy with a choice. The choice is the symptom of anxiety versus the postoperative defects and sequelae. Some of those sequelae are a lack of spontaneity, a loss of interest, of thoughtlessness, the loss of initiative and judgment, and some degree of euphoria.

I think all of us recognize that man's position in the animal kingdom is one of greatest domesticity. We have dealt with our fundamental instinctual trends with the greatest severity concomitant with what can be called civilization, which has been developed at a cost to every person of psychologic conflict. It is conflict between instinctual animal tendencies versus the social, economic and environmental prohibitory forces. This conflict manifests itself by anxiety which is universal. It is pathologic only in its degree, for we all have anxieties and all of us suffer. Sometimes the apparent suffering is not as great as indicated, and the evaluation of that suffering by an observer must be an extremely cautious affair. Sometimes the so-called suffering is actually pleasurable, as in the so-called maso-

chistic state. The possibility of this anxiety obtaining a certain pathologic threshold and becoming abnormal we all recognize. On the other hand, a certain quantity of anxiety is frequently the stimulus for a tremendous amount of productive and creative work, and when we think of some of the great men and women in our civilization we realize that their forceful drive to work was based on a great deal of anxiety.

It is obvious that if the anxiety and suffering, the things which one wants to relieve, are based on conflict, the rational basis of treatment is a psychologic therapy. This cannot always be done. It is sometimes very tedious and very costly, but if it were possible we would not hesitate to ask for more psychologic work in state hospitals rather than more operating rooms.

I think it is an extremely dangerous thing for man to assume that he is capable of judging quantity of anxiety and quantity of suffering, that he can tell exactly what dose of anxiety is normal and what is pathologic, and on that basis perform a mutilating brain operation. I think that the problem is much more dangerous with prefrontal lobotomy than with milder forms of therapy such as electric or metrazol shock, because after those forms of treatment the amount of recovery is considerable. But, once one cuts, there is no return. It is not possible to cut certain fiber pathways which function in the expression of certain individual conflicts. There is no such thing as microsurgery; it is an extremely macrosurgical procedure.

If we feel that the most rational therapy is a diminution of the severity of the conflict by psychologic methods, then by all means these must be tried first and thoroughly. I do not believe that the surgeon can assume the responsibility of being the operator at the behest of his neurologic and psychiatric friends and say "I did it because they told me to." He must assume the responsibility of insisting that before such operations are done all conservative means—and by "conservative means" I mean thorough going psychologic treatment—have been employed.

I think there is no question that this operation has a usefulness; but the delimitations of its usefulness have not been clarified. Older patients, perhaps people who have no chance whatever except to continue in state hospitals, are those on whom further experiments, since I think this is still an experiment, should be made. I perhaps may disappoint some, as I am not iconoclastic about this operation. I see its value. I think that perhaps something may come of it, but I do not think this is the time to disseminate it widely to the profession or to the public until we have learned much more of its limitations. I think its discussion should be limited to the specialists in the field.

DISCUSSION OF QUESTIONS

MODERATOR BUCY: Dr. Freeman, Dr. J. M. Nielsen of Los Angeles asks whether you have checked for such reflexes as Oppenheim's, Gordon's or Rossolimo's after this operation and, if so, what you have found, and also what about forced or reflex grasping.

DR. FREEMAN: These abnormal reflexes have been observed maybe a dozen times in the first forty-eight hours after operation. There have been 2 cases of hemiplegia, 1 with very definite reflex grasping, apparently caused by thrombosis or rupture of the anterior cerebral artery. This persisted to the end.

The most common neurologic signs after operation are masking of face, plateau speech and incontinence of the bladder.

MODERATOR BUCY: Dr. Palmer, Dr. A. E. Bennett of Omaha asks "A schizophrenic paranoid type, three years in the state hospital, had a partial remission after insulin shock for a short period of time and then relapsed. Might such a patient become a paroled patient following lobotomy?"

DR. PALMER: I think, provided the deterioration has been a fixed thing over a period of years and the response to energetic insulin therapy has been nil, it might be worth while to consider a prefrontal lobotomy. I should stress the importance of a reeducational phase following lobotomy. Certainly, the disruption of certain long-established habits by the cutting of association pathways calls for an effort to reeducate and to establish new patterns of behavior, since in the immediate postoperative phase the individual is very malleable and suggestible.

MODERATOR BUCY: Dr. Lyerly, Dr. John F. Fulton of New Haven, Conn., asks "Have there been any temporary or persistent changes in systolic blood pressure or any other circulatory changes after these operations?"

DR. LYERLY: One patient who had a severe involutional melancholia had a systolic blood pressure of around 200 before operation. With barbiturates, before operation, it could not be lowered below 160. After the operation it fell to 130 and has remained there since. There is no material change in blood pressure if the person had a normal blood pressure before operation.

DR. FREEMAN: If the blood pressure is normal before operation, it is likely to remain so during and after operation. We have followed 3 cases with hypertension of 190 to 240, and the blood pressure is now lower than it was four years ago.

MODERATOR BUCY: What would you say, Dr. Tarumianz, is the age limit? I presume he means the upper age limit.

DR. TARUMIANZ: The oldest patient operated on in our hospital was 66 years of age, and I believe that up to 70 should be considered.

MODERATOR BUCY: Dr. Tarumianz, Dr. Nichols asks "What happens to sexual behavior after frontal lobotomy?"

DR. TARUMIANZ: In our cases those who have been operated on have resumed normal sexual relationships.

MODERATOR BUCY: Dr. Freeman, Dr. Johnston asks "What insight do these patients who have been operated on show toward their former delusions, hallucinations, and so on?"

DR. FREEMAN: I think these patients do not recognize the nature of the delusions and the hallucinations. As I stated before, they lose the affective response to these, while the delusions continue of their own momentum for a while and then die out.

MODERATOR BUCY: Dr. Ralph B. Cloward of Honolulu asks "Has Dr. Freeman or Dr. Lyerly seen or studied gastrointestinal activity by fluoroscopy following the operation? Have stool examinations for blood been done to determine the possibility of erosions or ulcers?"

DR. FREEMAN: During the period of the operation the patient goes through the first side without any comment. Quite often with the first cut on the opposite side there is borborygmus and apparently reverse peristalsis with retching. Vomiting is continued at intervals for twenty-four or forty-eight hours, after which the symptoms subside. I think that among our patients there were some 30-odd who complained of indigestion before operation and not one of them had indigestion afterward.

DR. LYERLY: I have had some barium sulfate meals given patients before and after operation to test the motility of the stomach. In the few cases in which I have done this the motility of the stomach was essentially the same after operation as before. Some patients said that they had to be careful of what they ate before operation, and after operation they could eat anything and were hungry all the time. Constipation disappeared, and nausea and vomiting disappeared.

MODERATOR BUCY: Dr. Freeman, is it customary to use the instrument devised by Moniz or, if not, what type of instrument is now in use?

DR. FREEMAN: The Moniz instrument is ineffective and not particularly desirable because it leaves damaged tissue in place. At the present time we are using the Killian periosteal elevator to make a clean incision through the white matter of the frontal lobe.

MODERATOR BUCY: Is there any evidence that lobotomy might offer relief of postencephalitic behavior disturbances in children?

DR. FREEMAN: Rizzatti reported 5 or 7 cases of chronic encephalitic behavior disturbances, in 4 of which relief was obtained. I have had no experience.

MODERATOR BUCY: Have any of you had any experience with dextrose tolerance tests following lobotomy?

DR. FREEMAN: The test was unchanged in 1 case.

MODERATOR BUCY: Dr. Palmer, "Why isn't the effect of the operation as a shock the effective element?"

DR. PALMER: I would agree with Dr. Freeman and most of the others that the improvement is due entirely to the organic changes and the resulting alterations in function produced by the operation. The shock of unilateral lobotomy is almost as great as in the bilateral operation, and yet it has been repeatedly shown that unilateral lobotomy produces no change in behavior or in subjective feeling. I do not believe that the operation has any effect whatever as psychotherapy. All attempts at psychotherapy, including psychoanalytic procedures, reeducation, prolonged sanatorium care, suggestion, occupational therapy—every form of psychotherapy has been attempted over a period of many years in these patients without benefit. If they were to derive improvement from psychologic therapy associated with the shock of operation they would have obtained it from that which is inherent in metrazol therapy and in the solicitous care which goes along with insulin treatment.

DR. GRINKER: You are speaking now of your 5 schizophrenic patients?

DR. PALMER: Yes.

DR. GRINKER: That is quite a little different matter from the depressions that Dr. Freeman is talking about.

DR. PALMER: Dr. Grinker feels that many of the patients subjected to frontal lobotomy have not received

adequate or sufficiently deep psychotherapy. I should like to ask Dr. Grinker if he would tell us what success can be anticipated with psychotherapy in involutional melancholia and in the institutionalized schizophrenic patients.

DR. GRINKER: The question of percentage of success with psychotherapy is something that I cannot answer. It depends on the type of patient. It depends on the psychotherapist. It depends on a great many factors. What I have reference to is simply this: I feel that in many of these cases the psychotherapy has not been adequate. I recognize that there are cases in which no psychotherapy will help and one is forced to this or other radical procedures but always with a recognition of the extent of corollary defect. However, I am anxious about the future care of many of these patients, not especially those state hospital patients or institutionalized patients, but the general group of people with psychoses and psychoneuroses who will, if we are not very careful, be mutilated by this operation indiscriminately applied.

DR. TARUMIANZ: May I just say that I fully agree with Dr. Grinker. We must be careful with so radical a method. We should not consider any case for such an operation unless all necessary care and treatment have been given for at least two or more years.

DR. FREEMAN: I question, however, whether every patient before a prefrontal lobotomy should have the drastic treatment of metrazol, electric or insulin shock. I should like to ask Dr. Palmer in this connection whether he has also noticed that in the patients who recover after metrazol therapy and after electric shock therapy there is possibly the same temporal disorganization as following prefrontal lobotomy. I have seen patients who long after the shock therapy have said they couldn't remember time relationships, even though they had recovered substantially in other ways.

DR. TARUMIANZ: We have experienced that with our shock cases.

DR. PALMER: Yes, there is considerable disturbance of temporal orientation, there are even transient aphasia and transient amnesia following electric shock and following metrazol. These, however, have been of short duration, usually forty-eight hours, although in a man of 73 treated with electric shock the period of amnesia lasted for nearly three weeks. However, they have all experienced a restoration of the function of temporal orientation.

DR. FREEMAN: There is one other thing with regard to shock therapy. In a series of some 100 or 120 cases discharged from the hospital after shock therapy and followed over a period of six months to three years I have had 6 cases of suicide. After shock therapy a good many of these patients hate to come back for further shock treatment and some of them will take the quick way out rather than face that possibility. This fact, in addition to the other defects, the disasters, the fractured spines and spontaneous convulsions that occur following shock therapy, I think should make us a little cautious about saying "Well, we ought to try shock therapy first." Actually considerable damage can be done to the brain by shock therapy and we see that particularly following the prolonged comas produced with insulin.

GLANDULAR PHYSIOLOGY AND THERAPY

THE PARATHYROIDS—PHYSIOLOGY AND THERAPEUTICS

FULLER ALBRIGHT, M.D.

BOSTON

This special article is published under the auspices of the Council on Pharmacy and Chemistry. It is one of a series which will be published in book form as the second edition of "Glandular Physiology and Therapy." The opinions expressed in this article are those of the author and do not necessarily represent the views of the Council.—Ed.

NORMAL AND PATHOLOGIC PHYSIOLOGY OF PARATHYROID GLANDS

The parathyroid hormone has a marked influence on the metabolism of calcium and phosphorus. Its primary action, in my opinion, for reasons which cannot be gone into, is on phosphorus metabolism, and the changes in the metabolism of calcium are dependent on the preceding changes in the metabolism of phosphorus.¹

Calcium Metabolism.—The metabolism of calcium is considerably simpler than that of phosphorus. Over 99 per cent of the body's calcium is in the form of a calcium phosphate-calcium carbonate compound which is deposited in the organic matrix of bone and teeth. In addition, there are small amounts of calcium in body fluids. The calcium in the blood except for a negligible part is in two forms, calcium ions and calcium proteinate.² The parathyroid hormone apparently regulates the level of calcium ions. There is considerable circumstantial evidence that the stimulus for the parathyroid glands to produce more hormone is a serum calcium ion level below normal. Even when calcium is absent from the diet, a considerable amount is excreted in the urine, since the normal serum calcium value (10.5 mg. \pm 1 mg. per hundred cubic centimeters) is above the threshold (circa 7 mg.) for calcium excretion. Calcium is also excreted in the feces. There is evidence that fecal calcium represents not only calcium which has not been absorbed by the gastrointestinal tract but calcium which has been excreted into the gastrointestinal tract.³ The latter portion, however, is of small quantitative significance except in hyperthyroidism.³ Two other routes of calcium loss from the body are the lactating breast and the placenta. Since the amount of calcium which can be held in the body fluids is small and quite constant, it follows that if the calcium intake is greater than the calcium output the balance must for the most part be represented by the calcium deposited in bones or possibly in teeth. The converse must be true if the patient is in negative calcium balance.

Under normal conditions both calcium deposition and calcium absorption from bone are going on at all times. One process, to be sure, may be greater than the other, depending on the calcium balance as a whole. There is no such metaplasia of tissue in the teeth. It may be that there is a very slight interchange of calcium in the adult tooth, but, in my opinion, for all practical purposes this may be disregarded. When the tooth is being laid down there can be acalcification (i. e., absence of calcification) if the calcium metabolism in the body is faulty; once the tooth is formed, however, there is no decalcification. If tooth decay occurs during pregnancy, and it apparently does, the mechanism is not mobilization of calcium from the tooth to the blood stream, to the placenta, to the child.

3. Aub, J. C.; Bauer, Walter, C., and Ropes, M.: Studies of Calcium and Phosphorus Metabolism: III. The Effects of the Thyroid Hormone and Thyroid Disease, *J. Clin. Investigation* 7: 97 (April) 1929.

Phosphorus Metabolism.—Phosphorus, likewise, is found in large amounts in bones and teeth (calcium to phosphorus ratio, approximately 2 to 1), and in smaller amounts in body fluids. In the serum one is here concerned chiefly with phosphorus in the form of inorganic phosphate. It is customary to speak of this as "serum phosphorus" rather than to use the more clumsy expression "serum phosphorus as phosphate." The normal level for adults is 3.5 mg. plus or minus 0.5 mg. It is higher in children. There are, in addition, in the body many organic phosphate compounds, such as phosphoprotein, phospholipids and various phosphate esters, which liberate phosphate ions on hydrolysis. Thus, a positive phosphorus balance does not necessarily mean that phosphates are entering the bones.

Relation of Calcium Metabolism to Phosphorus Metabolism in Disease of the Parathyroids.—If one stops substitution therapy with parathyroid extract in a parathyroidectomized patient, four cardinal metabolic changes occur. There is first an immediate decrease in the phosphorus excreted in the urine; second, the serum phosphorus level rises; almost simultaneously the serum calcium level falls; finally, with the fall in serum calcium there is diminished excretion of calcium in the urine.¹ If one administers parathyroid extract to a normal person these same four metabolic functions are altered in the opposite directions; i. e., one obtains hyperphosphaturia, hypophosphatemia, hypercalcemia and hypercalciuria. There are two schools of thought as to the mechanism by which these four cardinal metabolic effects are mediated. One school holds that the hormone acts on bone tissue (notably osteoclasts) and tends to dissolve or otherwise remove calcium phosphate deposits from the bone.⁴ Such a theory might explain the hypercalcemia, hypercalciuria, and hyperphosphaturia; it does not explain the hypophosphatemia unless one hypothesizes some secondary adjustment. The theory to which I adhere is based on the hypothesis that the hormone affects phosphates in the circulating body fluids in such a way that their excretion in the urine is increased. This would explain the immediate hyperphosphaturia on administration of parathyroid extract and the resulting hypophosphatemia. Furthermore, because of the lowered level of serum phosphorus, it is contended that the serum would be less saturated with respect to calcium phosphate and there would be an increased tendency for calcium phosphate to enter the serum from the gastrointestinal tract or from the bone. This would lead to hypercalcemia, and finally the hypercalcemia would lead to hypercalciuria. It will be impossible to discuss the pros and cons of these two opposite and still unproved theories in the present article.

HYPOPARATHYROIDISM

Causes.—A decrease in the number of, or absence of, the parathyroid glands is most commonly due to accidental removal of some or all of these organs during thyroidectomy. Very rarely, the condition occurs idiopathically. Just why all four glands should disappear idiopathically is of considerable academic interest. In an autopsy in such a case all four glands were found to be present and grossly to have a normal appearance. However, histologic sections showed that the epithelial cells had been entirely replaced by fat cells.⁵ An intermediate stage in which the epithelial elements were much diminished and replaced by fat tissue has been described in a patient suffering from anterior pituitary deficiency.⁶ In hypopituitarism, however, one does not find clinical evidence of hypoparathyroidism, and I do not believe that idiopathic hypoparathyroidism is due to lack of some hormone from the anterior lobe of the pituitary. There is considerable evidence that the parathyroid may be functionally deficient shortly after birth and that convulsions

in an infant may be a manifestation of hypoparathyroidism.⁷ Of academic interest is a case recently reported of hypoparathyroidism in a child born of a mother with hyperparathyroidism.⁸ This suggests that the infant's parathyroids became compensatorily hypoplastic in intrauterine life.

Pathologic Physiology.—The most important chemical findings are the low level of serum calcium and the high level of serum phosphorus. In a parathyroidism the serum calcium may be as low as 5.0 mg. and the serum phosphorus as high as 12.0 mg. per hundred cubic centimeters. There should be no calcium excreted in the urine except in the very mild forms, as the serum calcium should be below the threshold for excretion of calcium (see earlier comment on this). The phosphorus excreted in the urine is often within normal limits. One expects hypophosphaturia only when the patient is adjusting from one degree to a lesser degree of parathyroid function.

Symptoms.—The most striking clinical feature of hypoparathyroidism is the increase in neuromuscular excitability dependent on the hypocalcemia, producing the symptom complex known as tetany. This phase of the subject is so well covered in all the textbooks that it will be mentioned only in passing here. The features of tetany are: carpopedal spasm, positive Chvostek, Trousseau and Erb's signs, laryngeal spasm and epileptic seizures, especially if the condition has been present a long time or if it occurs in very young children. Cataracts are present in almost all cases of long-standing duration, although it may take a slit lamp examination to find them. In many cases, however, they are sufficiently severe that their removal is required. Calcification of brain tissue is not an infrequent finding.⁹ I have seen this in a case in which no symptoms referable to the central nervous system had been observed and in a case in which there had been epileptic seizures. When hypoparathyroidism develops before the teeth have entirely formed, one finds aplasia or hypoplasia of the teeth from that point in their development at which the hypoparathyroidism came in.¹⁰ Thus, if the disease develops in a child at about the twelfth year of age, the teeth will be entirely normal except for blunting of the root ends of the cuspids, premolars and second molars and hypoplasia of the crowns of the third molars. Those are the last parts of the teeth to form. Changes of the nails and hair have been described,¹¹ but they are not present in all cases and their significance remains obscure. The bones in hypoparathyroidism are definitely more dense than normal, which is of considerable academic but of no clinical importance.¹¹

Differential Diagnosis.—Other conditions which cause tetany may be confused with hypoparathyroidism. For all practical purposes one may consider that there are two causes of tetany: hypocalcemia and alkalosis. As far as I am aware, there is no evidence that the tetany caused by alkalosis is due to some secondary change in the availability of calcium ions.

The nonparathyroid causes for hypocalcemia are rickets or its adult form osteomalacia, steatorrhea, and

renal insufficiency with phosphate retention. In rickets or osteomalacia the low value for serum calcium is characteristically coupled with a low, or in some instances normal, value for serum phosphorus. High values for serum phosphorus are most unusual. The serum phosphatase level, which is always normal or even low in hypoparathyroidism, is high in both rickets and osteomalacia. Steatorrhea, of which sprue is an example, probably leads to hypocalcemia, because vitamin D, being fat soluble, is dissolved in the unabsorbed fat; hence the condition results in hypovitaminosis D; the chemical findings in the blood are therefore those of osteomalacia. In addition, one may find evidence of a lack of other fat-soluble vitamins, notably vitamin K (hemorrhagic diathesis) and vitamin A (night blindness, keratosis pilaris).¹²

In renal insufficiency one finds phosphorus retention with a compensatory lowering of the serum calcium level. There is, however, in renal insufficiency as compared with hypoparathyroidism a lesser degree of hypocalcemia for the same degree of hyperphosphatemia. The probable reason why the serum can hold more calcium in proportion to the phosphorus in renal insufficiency is that there is almost invariably an associated acidosis. Furthermore, one seldom meets tetany in renal insufficiency with hypocalcemia because of the associated acidosis, which inhibits tetany. If one controls the acidosis, tetany may develop.

The commonest cause of tetany due to alkalosis is hyperventilation, usually due to some emotional disturbance. The diagnosis, though often missed, is very simple. The respirations are often quite deep but not so strikingly rapid; there may be a past history of similar attacks under emotional stress; the condition responds quickly to holding the breath or rebreathing in a paper bag; the urine, characteristically, is alkaline and contains normal amounts of calcium. The presence of calcium in the urine can be quickly verified by the aid of the Sulkowitch solution, which will be discussed under "Treatment." In hyperventilation the carbon dioxide-combining power of the serum may be only slightly reduced. The most significant change in the blood is a lowering of the carbon dioxide content of the arterial blood.¹³ A less common form of the tetany due to alkalosis is that following ingestion of large amounts of an alkali, in which one encounters an alkaline urine, calcium in the urine, high carbon dioxide-combining power of the serum and possibly a high value for serum total base. In alkalosis due to excessive loss of gastric contents, one again encounters an alkaline urine, calcium in the urine and an increased carbon dioxide-combining power of the serum, also a marked lowering of the serum chloride value.

Treatment.¹⁴—The tetany in the symptom complex of hypoparathyroidism is due to the low level of the calcium of the serum. The goal is to raise the level of calcium to normal without overdoing this and obtaining hypercalcemia. Thus, all that is needed is an agent to raise the serum calcium level readily to any desired degree and a simple method of gaging this level. Dihydrotachysterol fills the first need and the Sulkowitch test for calcium in the urine the second.

Dihydrotachysterol,¹⁵ like vitamin D, is a photochemical derivative of ergosterol. It was developed by Holtz in Berlin¹⁶ for the treatment of hypoparathyroidism. One can easily raise the calcium of the blood to any desired or even undesired level with this substance. Its mode of action is beyond the scope of this article.¹⁷

The Sulkowitch reagent¹⁸ is a solution containing oxalate radicals buffered at such a p_H that when an equal amount of the reagent is added to urine, the calcium will almost immediately come down as a fine white precipitate of calcium oxalate. If there is no precipitation there is no calcium, and the serum calcium level is probably from 5 to 7.5 mg. per hundred cubic centimeters. If there is a fine white cloud, there is a moderate amount of calcium, and the level of calcium in the serum is in the satisfactory range. If the precipitate looks like milk, the danger of hypercalcemia is present.

Once the diagnosis of parathyroid tetany has been made, dihydrotachysterol is administered until tests of the urine show moderate amounts of calcium. If large amounts of calcium appear in the urine, the dose is reduced and the danger of hypercalcemia is avoided. The patient makes his own tests and modifies the dose according to the results. I usually prescribe about 3 cc. of a dihydrotachysterol preparation a day until calcium appears in the urine; then the dose is dropped to a maintenance level—about 1 cc. three to five times a week.

This discussion has been slightly oversimplified. There are a few "ifs" and "buts" that must be added. Occasionally, a normal person who happens to be on a diet very low in calcium will show in a single specimen of urine practically no calcium. Almost any normal person shortly after drinking a large amount of milk will show an excess of calcium in the urine. Since one keeps patients with hypoparathyroidism on a diet high in calcium, one would expect them always to show hypercalciuria if their levels of serum calcium are normal. It thus turns out that if the dose is reduced when a large amount of calcium appears in the urine the blood calcium will be kept at a slightly subnormal level. This is probably all the better, since it further guards against hypercalcemia and since slight hypocalcemia is not deleterious.

A large number of measures other than the administration of dihydrotachysterol may be useful in the treatment of hypoparathyroidism.¹⁹ To be sure, treatment with this drug is so satisfactory that one may be disinclined to bother with the other measures. A few of the salient points will be mentioned. There should be a high intake of calcium and a low intake of phosphorus. Milk, though high in calcium, is contraindicated because it is likewise high in phosphorus. The dietary conditions are sufficiently met if the patient omits milk as a beverage from the diet and takes a teaspoon of calcium gluconate or of calcium lactate dissolved in water three times a day. Just as alkalosis causes tetany, so acidosis tends to alleviate

tetany. It is therefore helpful in some instances to make the patient slightly acidotic. Calcium chloride by mouth produces slight acidosis, since more chloride is absorbed than calcium. A favorite prescription in the past has been 10 cc. of a 30 per cent solution of calcium chloride diluted in water and taken three times daily after meals. Such a prescription produces slight acidosis and insures a high intake of calcium at the same time. It has been shown that thyroxin tends to raise the serum calcium level in hypoparathyroidism.²⁰ Since many patients with postoperative hypoparathyroidism are at the same time suffering from a slight thyroid lack, it is often wise to administer thyroid to the limit of tolerance. Although parathyroid extract has played a large part in the history of parathyroidology, it is not used routinely in the therapy of hypoparathyroidism. The drawbacks are that it is expensive, that it often causes a local reaction and that its effectiveness wears out, apparently because of the formation of an antibody.

In an acute emergency 10 cc. of calcium gluconate can be administered intravenously. It must be emphasized, however, that whereas the symptoms of tetany may be terrifying, the condition is seldom fatal. Laryngeal spasm is the one most dangerous manifestation.

If the blood calcium is kept normal in hypoparathyroidism, cataracts do not develop. Those, once formed, however, do not regress. The cause of the cataracts is apparently the hypocalcemia. Cataracts also occur in hypocalcemia without hypoparathyroidism (e. g., sprue).

PRIMARY HYPERPARATHYROIDISM

By "primary hyperparathyroidism" is meant a condition in which more parathyroid hormone is produced than is needed. By "secondary hyperparathyroidism" is meant a condition in which more parathyroid hormone is produced than is normal but this excess is needed for some compensatory purpose.

Causes.—Hyperparathyroidism may be due to a single adenoma of one of the four glands, to multiple adenomas or to hypertrophy of all the parathyroid tissue. In the first 50 cases of hyperparathyroidism proved to be such by operation or autopsy, at the Massachusetts General Hospital, the disease was due in 41 cases to a single adenoma, in 3 cases to two adenomas and in 6 cases to hypertrophy. By hypertrophy is meant a condition in which the amount of parathyroid tissue is about forty to one hundred times the normal. The histologic appearance of the tissue is entirely dissimilar from that seen in any other form of parathyroid disease.²¹ The individual cells have about five times the radius or about one hundred and twenty-five times the volume of a normal cell ($V = 4/3\pi r^3 = 4/3\pi \times 5 \times 5 \times 5 = 4/3\pi \times 125$). The histologic appearance is not in the least suggestive of hyperplasia, in which one finds cells of almost normal radius. The cause of hypertrophy of parathyroid tissue remains entirely obscure.

Pathologic Physiology and Diagnostic Considerations.—As in other conditions of overactivity of an endocrine gland, in hyperparathyroidism one can observe every degree of the disease. The slighter the

degree the less abnormal will be the chemical findings in the blood. It so happens that a very mild manifestation of the disease may lead to a fatal issue, hence it becomes important to recognize the mild forms. The serum calcium level is characteristically high (up to 18 mg. when the condition becomes severe) but may be within normal limits in the milder forms of the disease.²² It is important that the determination of serum protein be done in conjunction with that of serum calcium, since a normal level of serum calcium in the presence of a low level of serum protein is really abnormal. Of the two fractions of serum calcium, calcium ions and calcium as proteinate, it is the former which is primarily high in hyperparathyroidism; if the serum protein should be low, owing to some complicating condition, it might be that the level of serum calcium would be normal in spite of the fact that the calcium ions in the serum were increased.²² The serum phosphorus level in hyperparathyroidism is almost invariably low, 3.1 mg. or lower, unless renal damage is present. A normal person may have a low level of serum phosphorus on one determination, but it is characteristic of the patient with hyperparathyroidism that the level is consistently low. The calcium and phosphorus excreted in the urine are both increased. Again, however, there is an overlapping between normal and mildly hyperparathyroid states in the amount of calcium in the urine. If the hyperparathyroidism leads to bone disease, which it need not (see an earlier statement), the phosphatase level is increased, reaching 20 to 30 Bodansky units in severe forms.

There is a difference of opinion as to the cause of the bone disease in hyperparathyroidism. It is a fact that a patient may have severe hyperparathyroidism and still no clinical, roentgenologic or histologic evidence of bone disease.²² Those who believe that the parathyroid hormone acts directly on bone tissue would probably argue either that the aforementioned condition was of short duration or that some evidence of bone change would have been found had one examined the right bone tissue (e. g., trabeculae on the inside of the bone shaft rather than the cortex). This is not my interpretation. In my opinion, hyperparathyroidism brings about a change in the blood chemical balance which results in an increased excretion of calcium in the urine. Other things being equal, this increases the chances of the patient being in negative calcium balance. If the patient is in negative calcium balance, bone disease develops; if the patient happens to ingest as much calcium as is lost in the urine and feces, the calcium balance is not negative and bone disease does not develop. For all practical purposes, this usually comes down to whether the patient drinks milk. If he does, his calcium intake will be sufficient to keep him in positive calcium balance even if he has marked hyperparathyroidism.

Osteitis Fibrosa Cystica Generalisata.—Under normal conditions there is constant metaplasia of bone. There are trabecular surfaces where bone is being laid down and surfaces where bone is being absorbed. When the patient is in positive calcium balance, the former process outweighs the latter, and vice versa when the patient is in negative calcium balance. A decrease in bone tissue may result from increased absorption or from decreased formation of bone. The bone disease asso-

ciated with hyperparathyroidism belongs in the former category. The histologic evidence of bone absorption is an increase in the number of osteoclasts. Since the bones become much weakened, and since there is no fundamental disorder of bone repair processes, one finds evidence of bone repair (increase in osteoblasts) in conjunction with bone destruction. In other words, there is a marked increase in the metaplasia of bone. There results an increase in serum phosphatase, which in the absence of hepatic disease is an index of osteoblastic activity. The bone matrix which is laid down by the osteoblasts is calcified. The stroma of the bone marrow is also increased, causing fibrosis. Sometimes one sees solid tissue tumors composed of osteoblasts and osteoclasts. These are designated as benign giant cell tumors, or osteoclastomas. In addition, one finds cysts filled with fluid and lined with fibrous capsules. These are undoubtedly due to secondary degenerative changes. Likewise, one finds fractures. Most of the tumors and the cysts look like cysts on the roentgenograms and are usually so designated by roentgenologists.

Symptoms.—The symptoms of hyperparathyroidism can be distributed under three subheadings: (a) those due to bone disease, (b) those due to renal disease and (c) those due to hypercalcemia per se.

The symptoms which are produced by the bone disease can readily be inferred from what has already been said. Any bone tumor which on biopsy turns out to be a benign giant cell tumor (osteoclastoma) may be evidence of underlying hyperparathyroidism. Such a tumor has a special predilection for the jaw; when it occurs there, it is called an epulis. Not every epulis, however, is due to hyperparathyroidism. Almost any skeletal manifestation—a spontaneous fracture, a decrease in height due to crushing of vertebrae, a pain in the back, tenderness in the shins—may be the first symptom of the disease.

Because of the increased amounts of calcium and phosphate excreted in the urine, the patient with hyperparathyroidism is predisposed to the formation of calcium phosphate or calcium oxalate urinary calculi.²³ Indeed, the symptoms associated with nephrolithiasis are the commonest first manifestation of the disease. Calcium salts may be deposited also in the pyramids (nephrocalcinosis) and lead to renal insufficiency. Such deposits give a characteristic roentgenographic appearance which is quite pathognomonic of this disease. Polyuria and polydipsia are rather constant and may become so severe in some patients as to lead to the diagnosis of diabetes insipidus. The cases in which polydipsia is most marked are of course the ones in which renal calculi are least apt to develop.

Just as hypocalcemia causes increased neuromuscular excitability, so hypercalcemia leads to decreased excitability. In patients with very high serum calcium there are certain symptoms apparently due to the high serum calcium per se. These patients feel tired, lose weight and are constipated. These symptoms are too indefinite to help in the diagnosis, but after the condition is corrected the relief from them is quite striking.

Parathyroid Poisoning.—By "parathyroid poisoning" is meant a sort of hyperhyperparathyroidism. If one administers parathyroid extract in large quantities to a dog, death will occur in two to three days, and at autopsy there will be calcium deposits in the alveoli of

the lungs, the mucous membranes of the stomach and the kidneys.²⁴ The sequence of events apparently is as follows: an increasingly high level of serum calcium, inspissation of the blood, an acute failure of the kidneys to excrete phosphates, a rapid rise in serum phosphorus, a combination at the same time of high serum calcium and high serum phosphorus, a precipitation of calcium phosphates into the tissues and chemical death. Patients with hyperparathyroidism seldom have such a degree of the disease that parathyroid poisoning develops. The condition, however, does occur occasionally.²⁵ It is sometimes precipitated by faulty therapy. If the serum calcium is near the critical level, where a slight increase in it would precipitate parathyroid poisoning, it may so happen that a diet high in calcium would make the difference. In my opinion, the patient with severe hyperparathyroidism should be kept on a low calcium intake until there is no danger of parathyroid poisoning. One's first impulse after seeing the decalcified bones is to insure that the patient's intake of calcium shall be high; this may be fatal.

Differential Diagnosis.—In this section will be discussed only those bone diseases which might be mistaken for that due to hyperparathyroidism.

Osteoporosis belongs in that category of bone diseases in which there is too little bone because the formation of bone is decreased. Furthermore, the lack of bone formation is due not to a failure of calcium salts to be deposited in the organic matrix (compare osteomalacia) but to a failure of the osteoblasts to lay down an organic matrix. The disturbance, therefore, is not really one of calcium metabolism but one of tissue metabolism. The serum calcium and phosphorus values are normal, and the serum phosphatase is not elevated. There is one important exception to this statement. Children have a more unstable calcium equilibrium than adults and apparently develop work hypercalcemia due to atrophy of disuse. One finds this condition in children in whom a large part of the skeleton has been isolated from stresses and strains by infantile paralysis (personal communication, Dr. William J. Orr) or by a plaster cast (unpublished). The calcium excretion in the urine may be increased in the early stages of the disease, when it may give rise to renal stones. The condition when not due to atrophy of disuse or advanced age is almost confined to women past the menopause and has a predilection for the bones of the spine and the pelvis. The skull is very seldom involved.

Osteomalacia, like osteoporosis, belongs in that category of bone diseases in which there is too little formation of bone. Here the lack of formation is not due to hypoplasia of the osteoblasts but to a failure of calcium salts to be deposited in the organic matrix. In this country the condition is extremely rare and found only in association with steatorrhea. The serum calcium is normal or low; the serum phosphorus is almost always low; the serum phosphatase is high. There is no increase in the calcium excreted in the urine; if anything, it is considerably decreased.

Paget's disease differs from osteitis fibrosa generalisata in that it is a circumscribed disease. Where the bone is normal, it is absolutely normal; where it is abnormal, it has many things in common with osteitis

fibrosa, notably the marked increase in metaplasia of the bone. The roentgenographic appearance of the individual bone lesions in Paget's disease is almost always pathognomonic. To be emphasized are the coarse trabeculation, the marked tendency of the bones to be expanded and the sharp demarcation between normal bone and abnormal bone. The serum calcium and phosphorus levels are normal; the serum phosphatase level is higher for a given degree of bone disease than in any other condition.

There is a syndrome characterized by osteitis fibrosa disseminata (polyostotic fibrous dysplasia²⁶), precocious puberty when it occurs in females, and areas of brown pigmentation.²⁷ Patients with this syndrome are frequently operated on in the belief that they have hyperparathyroidism. The diagnosis should offer no difficulty. The condition is not generalized but regional. This should immediately make one doubt the presence of an endocrine cause. The roentgenographic appearance of the bone is only superficially suggestive of that seen in hyperparathyroidism. There are areas of increased density as well as areas of decreased density. The serum calcium and phosphorus levels are normal; the serum phosphatase is high if there is a marked degree of the bone disease. The areas of brown pigmentation do not occur in all cases; the precocity mentioned occurs only in females.

Multiple myeloma can produce a clinical picture which may be most difficult to distinguish from that of hyperparathyroidism. The roentgenographic appearance of the bones can be quite similar, although in most instances of multiple myeloma the lesions are more sharply demarcated. For example, one expects punched-out areas in the skull rather than a diffusely "moth-eaten skull." The serum calcium can be high in myeloma; when it is, the calcium excreted in the urine is also high, and nephrolithiasis may be present. The high serum calcium is usually coupled with normal or high serum phosphorus. In some cases, however, the serum phosphorus is low, just as it is in hyperparathyroidism. The presence of large amounts of Bence Jones protein in the urine is strong evidence for myeloma; absence of this protein means little, as in only 15 of 30 cases of proved myeloma was it found.²⁸ Whether small amounts of this protein may be present with the bone disease of hyperparathyroidism is still questionable, as in those cases in which it has supposedly been found the most rigid criteria probably were not applied. Of course, the presence of plasma cells in the peripheral blood or a positive finding in a sternal biopsy or on sternal puncture are strong evidence for myeloma. The serum phosphatase is rarely if ever elevated in cases of multiple myeloma, an important differential point.²⁸

Metastatic malignant neoplasm offers less difficulty in the differential diagnosis. The roentgenographic appearance is quite distinctive. The serum calcium may be high, and there may be hypercalciuria and renal stone formation. The serum phosphorus level is usually normal, very occasionally elevated and occasionally lowered. The phosphatase level may be elevated. A primary

source should be looked for, and is apt to be in the breast, prostate, kidney (hypernephroma), bronchus or thyroid.

Other less common conditions which have been confused with hyperparathyroidism are: xanthomatosis, Gaucher's disease, lymphoma, benign metastasizing hemangioma, osteogenesis imperfecta, chronic radium poisoning and renal osteitis fibrosa generalisata (see under "Secondary Hyperparathyroidism").

Treatment.—It will be impossible to discuss treatment here in any but the most superficial manner. It is important to remember that whereas the symptoms due to bone changes may be the most striking feature of the case, the ultimate prognosis will depend on the extent of the renal damage. Most of the changes in the bones, exclusive of the cysts, are reversible; however, once the kidneys are sufficiently damaged as a result of nephrocalcinosis, recovery will not take place. There is even evidence that sometimes the renal condition is progressive after its cause has been removed.²⁹ Therefore, when a patient with severe hyperparathyroidism is first seen, fluids should be forced, and milk should be withdrawn from the diet to avoid further nephrocalcinosis, not to mention the danger of parathyroid poisoning (already emphasized). Although the bone lesions can be made to regress with a high calcium diet,³⁰ this is not to be recommended.

Since no satisfactory medical treatment for the condition has yet been devised, the main therapeutic indication is to remove surgically the etiologic factor or part of it. This requires an especially trained surgeon, not just a "good thyroid surgeon." If the condition is due to one or even two adenomas, and if the serum phosphatase level is normal (i. e., no bone disease), the indication usually is to remove the tumor or tumors. If, however, the pathologic change under otherwise similar conditions is hypertrophy of all parathyroid tissue, the procedure is to remove three of the parathyroid glands and all except 200 to 300 mg.³⁰ of the fourth.

If in a patient with marked bone disease and high serum phosphatase (20 Bodansky units or over) one removes all of the parathyroid tumor, there will be immediate cessation of bone destruction while bone formation continues at its terrific speed. This process will result in the calcium and phosphorus being sucked into the bones from the blood serum, with an increase in the hypophosphatemia and with production of marked hypocalcemia and severe tetany.²² The latter in the final analysis is not hypoparathyroid tetany, in which one has too little parathyroid tissue but normal bone. It is a much severer condition because of the "hungry bones."³¹ This form of tetany, when it occurs, will not respond to any of the usual measures of treatment and requires constant intravenous administration of a solution of calcium gluconate. At the Massachusetts General Hospital, it has been the rule not to remove the entire tumor in the patient with high serum phosphatase, unless there is some extenuating circumstance.

Another important consideration in deciding how much parathyroid tissue to leave behind is the degree

of renal damage. In the presence of marked damage one leaves behind much more tissue than one otherwise would. The rationale is discussed under "Secondary Hyperparathyroidism."

The postoperative course should be an important subject of discussion in this section, but it will have to be omitted because of lack of space.

SECONDARY HYPERPARATHYROIDISM

There are at least two conditions in which more parathyroid hormone than is normal is needed, for compensatory reasons: rickets (or osteomalacia) and renal insufficiency.

With vitamin D insufficiency (rickets and osteomalacia) there is interference with the absorption of calcium from the gastrointestinal tract; this tends to cause a lowering of the serum calcium level, and this tendency, in my opinion, is met by hyperfunction of the parathyroid glands, the stimulus being the low level of serum calcium; the increased production of parathyroid hormone leads to a decrease in serum phosphorus; the net result is that the serum calcium level remains normal and the serum phosphorus level becomes low.³² In patients with rickets or osteomalacia in whom serum calcium is low and serum phosphorus normal the compensatory parathyroid hyperfunction has not taken place. In patients in whom serum calcium and phosphorus are both low the hypocalcemia has occurred in spite of the hyperfunction of the parathyroid glands.³²

Secondary Hyperparathyroidism in Renal Insufficiency.—In patients with renal insufficiency in whom there is retention of nonprotein nitrogen there is almost always retention of serum phosphorus. Such persons post mortem have hyperplasia of all four parathyroid glands.³³ It is my opinion that the sequence of events is as follows: (a) renal insufficiency, (b) phosphate retention, (c) tendency toward a low level of serum calcium and (d) hyperplasia of the parathyroid glands to meet this tendency. In rare instances in which the condition is of long duration it may be accompanied by osteitis fibrosa generalisata³⁴ and may be confused with primary hyperparathyroidism. It is probably the secondary hyperparathyroidism which prevents most patients with renal insufficiency from having severe tetany.

There is an important corollary to the foregoing discussion which has considerable bearing on the treatment of some patients with hyperparathyroidism. It is theoretically possible that the following sequence of events might take place: (a) parathyroid adenoma producing primary hyperparathyroidism, (b) renal damage with phosphate retention and (c) a state of affairs in which the amount of secondary hyperparathyroidism needed because of the renal damage equals or exceeds the amount of primary hyperparathyroidism present. When this third stage has been reached, it is obvious that it would be harmful to remove the parathyroid tumor. The most important practical point to be gleaned from the foregoing discussion is that one should remove less parathyroid tissue than otherwise in patients with hyperparathyroidism and renal damage.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
HOWARD A. CARTER, Secretary.

"ALTEX" MATTRESS AND PILLOW ENCASINGS ACCEPTABLE

Manufacturer: Expert Bedding Company, 3355 North Halsted Street, Chicago.

The "Altex" Mattress and Pillow Encasings are intended for use by allergic patients sensitive to bedding dusts or the materials ordinarily used in the manufacture of mattresses and pillows.

"Altex" mattress and pillow encasings are made of a 60 by 112 count mercerized, white shirt type broadcloth, backed and bonded with a slow oxidizing, pigmented steam calendered rubber, impregnated with a deodorant. "Altex" cloth is backed in small quantities, in order that the patient may be supplied with constantly fresh material.

Mattress Closure and Interior Flap.—The mattress has an interior flap that acts on the weight principle (i. e., the weight of the mattress presses the flap down and holds it in place). After the flap is in place, the cloth-covered slide fastener is drawn shut and the exterior is lowered to cover the slide fastener. The instructions designate that "the casing opening should always be at the foot end of the bed to prevent any escaping material from getting to the patient."

Pillow Closure and Interior Flap Sheath.—The pillow interior flap sheath is used as a block for any heavy dirt or dusts; the weight principle is again utilized here, as in the mattress encasing.

Finishing and Sewing of Mattress Encasings.—Center seams are bias bound. All sewing is first done in the raw seams, which are then bias bound, a double stitch being made to insure tightly closed seams and to prevent possible leakage.

Finishing and Sewing of Pillow Encasing.—All seaming and binding is done on the inside of the encasing.

All sewing is done on a special sewing machine, producing a tight number 401 double lock stitch, carrying approximately nine stitches per inch; mercerized 0.3 natural thread is used.

Tests for Abrasion.—"Altex" cloth has a higher rating than two like products on the market.

Tests for Boiling.—Perspiration and soap boiling tests were made in the standard perspiration solution used by rubber chemists, and soap tests were made by boiling samples in 2 per cent soap solution for a period of twenty hours; the results were shown to be negative.

Water Test.—Small bags were sewn and filled with water. Tests showed that in the beginning there was a small drip; after two hours there was considerable swelling of the threads and seams, and thereafter the loss was by evaporation alone.

"Altex" encasings are fully guaranteed for one year from the date of shipment against deterioration, rips and such other factors as may be the result of faulty material and manufacture.

"Altex" encasings are sold on recommendation of the physician alone. None are sold through the avenues of retail stores.

The encasings were examined by the Council and were found to be well made and of good design. Each detail of the construction such as the sewing and the design of the flap inside and outside of the zipper fastening were good.

The Council voted to accept the "Altex" Mattress and Pillow Encasings for inclusion on its list of accepted devices.

"Altex" Mattress and Pillow Encasings.

OPERATION FOR RELIEF OF PAIN

Operations for the relief of pain are an important part of the rapidly developing field of neurologic surgery so intensively stimulated and developed by the late Harvey Cushing. Spiller¹ in 1905 suggested the possibility of relieving intolerable pain from the body by interrupting the pain pathways in the spinal cord. This procedure, called "chordotomy," was apparently first performed by Spiller and Martin² seven years later. Frazier³ in 1920 published a report of the first large series of cases in which pain was relieved by this means. The pain in all these cases was intractable; the cause in nearly all of them was inoperable cancer. In a report recently published in *THE JOURNAL*, Grant,⁴ an associate and a successor of Frazier, has reviewed the history of the operative relief of pain. Chordotomy, while effective in relieving pain from the torso and lower extremities, is not especially successful when pain is high in the arms or neck. The severance of individual sensory fibers is another method for the surgical relief of pain although applicable only in special locations, and its value is amply attested by the remarkable triumph often achieved in patients with tic douloureux and cardiac, pelvic and other pains.

A new operation for the relief of pain at the higher levels has been reported by Schwartz and O'Leary⁵ of Washington University School of Medicine. The approach is cerebellar and consists of section of the pain pathways in the medulla at the level of the inferior

olive. In the first case the relief from pain was immediate. Two days after operation, however, the patient died; necropsy showed extensive carcinomatosis of the lung. Important observations were made in this case on the central nervous system. By correlating anatomic and clinical data obtained from this patient it was possible to establish the location in the medulla of the pain fibers to the different parts of the body, and it was possible to demonstrate for the first time the topical localization of pain fibers within the spinothalamic tract of the brain stem. It also proved, for the first time, the feasibility of the procedure for the relief of pain located in the arms, chest and neck. In the second case the postoperative convalescence was uncomplicated, and complete alleviation of pain was obtained in the right chest, shoulder and axilla. Possibly wider application for this procedure than the relief of pain in inoperable cancer is suggested by a third instance cited by Schwartz and O'Leary; a patient with Raynaud's disease, operated on by J. C. White of Boston, enjoyed complete relief from pain.

These studies have successfully achieved two objectives. First, they provide another tool in the relentless battle against intolerable effects of pain located in parts of the body hitherto inaccessible to surgical relief and thus extend the usefulness of this important therapeutic procedure. Second, they contribute additional information concerning the exact localization of pain pathways in the central nervous system and thus bring closer to realization an accurate "wiring diagram" of the important nerve impulses which control human activity.

FRONTAL LOBOTOMY

Elsewhere in this issue of *THE JOURNAL* (page 517) is a condensed report of a panel discussion on frontal lobotomy held before the Section on Nervous and Mental Diseases at the annual session of the American Medical Association in Cleveland on June 5. In frontal lobotomy most of the fiber tracts are cut in the white matter of both frontal lobes, considerably anterior to the motor cortices. This procedure is said to be effective in removing the anxiety and in abolishing the responses (suicidal, homicidal and so on) to the delusions and hallucinations in certain depressive states, such as involutional melancholia, and in certain of the more agitated schizophrenic states. Psychotic persons subjected to this procedure also seem to lose much of their concern with self and with their own visceral and mental activities; they develop a more normal, healthy attitude toward their environment.

In spite of these "improvements" in the mental condition of some patients this operation should not be considered capable of transforming a psychotic personality into a normal one. Even in our present state of ignorance concerning the frontal lobes there is ample evidence of the serious defects produced by their removal in nonpsychotic persons (Penfield and

Evans,¹ Brickner,² Goldstein,³ Halstead⁴). It is inconceivable that any procedure which effectively destroys the function of this portion of the brain could possibly restore the person concerned to a wholly normal state. In a few instances frontal lobotomy has resulted in convulsions, which did not appear until months or even years after the operation. As yet the nature and magnitude of the defects attendant on frontal lobectomy or frontal lobotomy are only superficially understood. Their nature must be thoroughly determined and their degree accurately assessed if we are to balance intelligently the beneficial results of this procedure against the alterations in personality which the procedure itself may produce. Only thus can frontal lobotomy be truly evaluated and assigned a proper place in the therapeutic armamentarium of the psychiatrist.

An emotional attitude of violent unreasoning opposition to this form of treatment would be inexcusable. True it is a "mutilating" operation and it does result in certain defects in personality and behavior. However, much surgery is "mutilating" in the sense that some ordinarily normal tissue is removed in order to achieve a beneficial result. This is true, for instance, of appendectomy, gastrectomy, sympathectomy and the removal of cerebral cortical scars for the relief of localized convulsions. Much abdominal surgery also results in "defects." Moreover, only severely mentally ill patients who are permanently incapacitated are subjected to this form of treatment. Frontal lobotomy has not been advocated for "normal" persons.

In this panel discussion, abstracted in this issue of *THE JOURNAL*, sufficient information is presented to warrant further experience with this procedure. Until adequate evidence is available, this operation remains of necessity an experimental procedure. Its use may well be restricted to persons who have received the benefits, if any, of all less drastic forms of therapy that are recognized by modern psychiatry; to persons in whom there is no doubt, because of the long duration and the nature of the illness, that their condition is both serious and otherwise permanent. However, it does not seem reasonable to demand that all patients must be previously submitted to other drastic, often "mutilating," procedures such as an insulin, metrazol and electric shock, which like frontal lobotomy are also still in the experimental stage and in the process of assessment. The problems concerned in frontal lobotomy are susceptible of solution only by those specially trained in the fields of psychiatry, psychology and neu-

rology. Certainly such an operation cannot be widely applied to all forms of the neuroses and psychoses. Neither should it be utilized except by specially trained investigators situated in centers equipped to study such methods under adequate control. In the present experimental stage there is no excuse for dissemination of discussions or of any statements laudatory of this procedure to the general public. No doctor can yet assert that this is or is not a truly worthwhile procedure. The ultimate decision must await the production of more scientific evidence.

Current Comment

CHEMICAL NATURE OF BLOOD AGGLUTINOGEN

The isolation and identification of the human blood group specific B-agglutinin has just been reported by Witebsky,¹ a refugee physician from the Institute for Experimental Cancer Research, Heidelberg, Germany, at present a member of the research staff of the Buffalo General Hospital. Determination of the chemical nature of this hereditary hapten is of both theoretical and clinical interest. Following the development of modern methods of determining incompatibilities to blood transfusion in patients, blood group specific A-substance was detected in the urine, saliva and gastric contents of subjects belonging to the type A blood group. The first successful isolation of this hereditary agglutinin, however, was made from horse saliva. From 1 liter of this saliva (obtained by therapeutic salivation) Landsteiner² isolated 5 mg. of a mucin-free, protein-free, coagulable substance which would specifically inhibit type A rabbit hemolysin and type A human isohemagglutinin. Chemical analyses showed that this specific erythrocytic hapten is a carbohydrate belonging to the same general category as the type-specific bacterial polysaccharides. Landsteiner's chemical technic was afterward improved by Goebel,³ who was able to isolate from 1 to 3 per cent of type A erythrocytic polysaccharide from commercial peptone. This result was of main clinical interest at the time, since it suggested a fertile source of technical error in the immunochemical classification of pneumococci and other capsulated bacteria. Numerous unsuccessful attempts were made at about the same time to isolate B-substances from human blood. It was not till the discovery that type B hapten exists in particularly high concentration in the gastric juice of subjects belonging to blood group B that these attempts were successful. From 110 cc. of pooled blood group B gastric juice Witebsky and his co-workers were able to isolate 13.5 mg. of type B erythrocytic polysaccharide. In dilutions as high as 1:2,000,000 the Witebsky hapten completely inhibits isoagglutination of human B-group cells by A-group human serum. Parallel titrations suggest that the concentration of type B erythrocytic polysaccharide

is in the neighborhood of 1:1,000 in group B gastric juice. The main interest in Witebsky's research lies in its promising clinical applications.⁴ Contrary to earlier clinical beliefs, it is now increasingly evident that transfusion of O blood into A and B patients often causes serious toxic reactions. This toxicity is presumably due to anti-A or anti-B isoagglutinins and isohemolysins invariably present in O bloods. The titer of these isoantibodies may vary greatly, but they are often present in sufficiently high concentration to cause demonstrable test tube reactions with type A, B or AB recipient erythrocytes. In recognition of this danger, a law has been recently enacted in New York State in which "careful titration of the anti-A and anti-B properties of O blood is required before O blood may be given to individuals belonging to other groups." Witebsky finds that O blood toxicity for type A recipients can be completely inhibited by neutralizing the anti-A isoantibodies with A erythrocytic carbohydrate. In ten human blood transfusions thus far made with A neutralized O bloods toxic reactions that could be attributed to anti-A isoagglutinin have not been noted. Calculated from his reported data, 2 mg. of A carbohydrate is sufficient to detoxicate 500 cc. of O blood of high anti-A titer. In the opinion of Witebsky and his colleagues, the addition of A substance to O blood is in all cases clinically harmless. Whether or not his newly isolated B erythrocytic carbohydrate is equally effective with type B recipients has not yet been determined.

DENTAL CARIES IN RURAL CHILDREN

The connection between dental caries in children and the reduced cutaneous production of vitamin D from solar radiation due to climatic factors has been studied by East and Kaiser.¹ They took into consideration the mean number of hours of sunshine annually, the latitude and the mean winter temperature. Next they selected the caries rates for white children residing in three hundred and fifty-eight rural or semirural counties of twenty-four states of the United States as determined by data collected under the direction of the American Dental Association and the United States Public Health Service.² The survey comprised 581,708 children about equally divided according to sex and classified in age groups of 6 to 8, 9 to 11 and 12 to 14 years. Rural children were selected because of the greater uniformity in ethnology, food, housing and living conditions and in the amount of dust and smoke in the air. The study was restricted to white children to exclude, as far as possible, the variable which skin pigmentation might introduce. Only caries in permanent teeth was considered. The data for the mean number of annual hours of sunshine in the various counties and for the mean winter temperature were taken from records of the United States Weather

Bureau. Of the three hundred and fifty-eight counties one hundred and ninety had more and one hundred and sixty-eight had fewer than two thousand six hundred hours of sunshine annually. Groups living in counties where most sunshine prevailed had in every instance the lowest rates for caries. One hundred and thirty-four counties had a mean winter temperature higher and two hundred and twenty-four a mean temperature lower than 30 F. Groups living in zones in which the mean winter temperature was below 30 F. had higher rates for caries than those who lived where the mean temperature was higher. One hundred and sixty-nine counties were north and one hundred and eighty-nine were south of latitude 40 north. In every instance the children living in the northern zone had a higher mean rate for caries. To determine the degree of relation between the caries rates and the three climatic factors of sunshine, latitude and winter temperature, the correlation coefficients of all possible combinations were computed by means of the partial regression equation,³ an intricate statistical formula, and the results are tabulated by the authors. The lowest values in their sunshine series indicated that each additional hundred hours of sunshine was associated with a decrease of 3.92 ± 0.8 and 4.7 ± 1 per cent from the mean rates of caries in the permanent teeth of boys and girls, respectively, in the 9 to 11 year groups. The highest values were in the 6 to 8 year groups, which showed respective decreases of 7.4 ± 1 and 6.3 ± 1.6 . The values for the 12 to 14 year groups were intermediate. In their latitude series each increase of 1 degree of latitude was accompanied with a percentage increase of 2.7 ± 1.3 in the caries rates for boys of 6 to 8 years. In girls of the same age the increase of the mean rate was 1.1 ± 1.2 per cent. The other age groups showed important and statistically significant percentage increases. The lowest value for the groups of 9 to 11 and 12 to 14 years was 4.1 ± 1.1 per cent for each degree of latitude. In the evaluation of the relation of winter temperature to caries rates it was found, after the overlapping influences of sunshine and latitude had been eliminated, that winter temperature exerted little effect on the caries rates where boys were concerned and on those for girls in the age groups from 9 to 11. This study, accordingly, confirms previous evidence that a significant relation seems to exist between the incidence of dental caries and the amount of sunshine and the latitude. Winter temperature was an important climatic factor only for girls in the age groups of 6 to 8 and 12 to 14 years. This difference in incidence, the authors speculate, may be due to the fact that the youngest girls are kept indoors in cold weather while boys of the same age are not. Similarly, rural girls between 12 and 14 years may have indoor duties while boys of the same age find their recreation and tasks outdoors. The results of this study of environmental factors in relation to dental caries, they say, are in accord with those obtained in controlled vitamin D therapy experiments and in artificial ultraviolet irradiation.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

ARMY IN BEST PHYSICAL SHAPE SINCE START OF EMERGENCY

According to health records from all nine corps areas, the Army of the United States is in the best physical shape it has been in since the emergency began, the War Department announced, July 31. No epidemic diseases are prevalent. During the second week in July the admission rate to all Army hospitals for all causes was the lowest of the year. The rate went up slightly during the third week, but blistered heels and similar minor ailments made the difference.

For the last two months respiratory diseases have been no higher than the ten year rate for the preemergency army. This ten year rate is considered by Army medical men to be excellent.

At present the rate of men off duty because of diseases is 12 per thousand. In the Army a man is either on duty or in

a hospital, so the same causes that would force a civilian to take it easy for a half day send a soldier to the hospital for attention.

The Surgeon General's Office is notified by telegraph of each case of such serious epidemic diseases. In the last seven months only 12 cases were reported from all corps areas.

AIR CONDITIONING FOR ARMY BARRACKS

The War Department announced on July 31 authorization for the installation by the Engineer Corps of air conditioning equipment, in the form of humidifying coolers, at army air corps installations in high temperature zones, at a total cost of about \$500,000. Investigations conducted by Engineer Corps officers in the field indicated a temperature drop from 10 to 20 degrees F. when the coolers were used. They are of simple construction and easily installed. Consisting of a metal cabinet filled with fine cut porous substance such as excelsior, the cabinet is attached outside a window. The filler material is thoroughly wet down with water, and a fan on the room side of the cabinet draws wet or humid air through it into the room. Evaporation of this moisture lowers the room temperature. Theaters, chapels, barracks, hospitals, bachelor officers' quarters, cadet barracks and school buildings on the selected posts will be equipped with coolers. Coolers will be installed at Las Vegas Airfield, Nevada, Phoenix-Higley Airfield, Luke Field and Tucson Airfield, Arizona, and Muroc Bombing Range, Victorville Airfield, Bakersfield Airfield, Fresno Airfield, Taft Airfield, Merced Airfield and Lemoore Airfield, all in California. The work will proceed immediately.

PHYSICAL EXAMINATIONS FOR OFFICERS ELIMINATED

During the present emergency the annual physical examination of officers, warrant officers and nurses of the Regular Army, and the usual physical examination in the event of temporary promotion for all officers in the Army of the United States, except Air Corps officers, have been eliminated, the War Department announced on July 31.

Previously, every officer, warrant officer and nurse of the Regular Army was required to undergo a physical examination each year, and on promotion an officer again received a physical examination. The new policy dispenses with these examinations except in the case of Air Corps officers, who will continue to be examined twice each year. Officers of the Regular Army who receive permanent promotion must still receive physical examinations.

The physical examinations were eliminated because of the excellent physical condition of all officers at the start of the emergency. Regular Army officers have had their annual physical examination and were found unusually fit. Officers in other components of the Army received rigid physical examinations on induction into federal service.

DEFENSE ACTIVITIES OF NAVY'S MEDICAL SERVICE

The Bureau of Medicine and Surgery of the U. S. Navy has established a section of industrial health to help increase production in the Navy's industrial shore establishments by keeping preventable accidents and industrial disease at a minimum. Sixteen medical officers recently completed courses of postgraduate instruction at the schools of public health of Columbia University in New York and Harvard University in Boston. These officers were to be assigned to the shore establishments. The Naval Medical School is also training and equipping mobile epidemiologic and sanitary units, which may be sent to meet health emergencies wherever the Navy's forces are distributed. The central laboratory in the Naval Medical School will serve as a base for these units to carry out investigations too complicated to be done in the field. It is pointed out that the purpose of this plan is twofold: first, the eradication and prevention of spread of infectious diseases and, second, the accumulation of knowledge which should be of value in the future.

PUBLIC HEALTH SERVICE TO FIGHT VENEREAL DISEASE

A nationwide venereal disease control program in areas of military and defense industry concentration was announced on July 27 by WPA Commissioner Howard O. Hunter. The program has been approved by the President as a unit of the WPA national defense research and records assistance project, for which an allocation of \$5,015,864 was made several months ago. The United States Public Health Service will act as the official sponsor.

Surg. Gen. Thomas Parran said that the purpose of the program is to provide assistance to state and local health authorities in (1) bringing under immediate treatment selectees who have been rejected or deferred by their local Selective Service boards because of syphilis or gonorrhea and making these men available for military service on completion of treatment; (2) tracing

the sources of infection and rendering potential spreaders of venereal disease noninfectious through prompt and adequate treatment; (3) placing treatment facilities for gonorrhea on a par with those for syphilis and providing medical and public information on new chemotherapeutic methods for curing gonorrhea, and (4) establishing emergency venereal disease control programs in "boom" towns where regular public health facilities are insufficient to cope with the problem.

Dr. Parran cited findings of Selective Service medical examination which showed that 6 per cent of the draftees examined were infected with syphilis or gonorrhea.

Mr. Hunter pointed out that WPA workers have engaged in venereal disease control work in many parts of the country during the last six years. A check made several months ago revealed that about four thousand project employees in thirty-three states and the District of Columbia were assisting in the operation of four hundred and thirty-one public clinics for the treatment of venereal diseases. This assistance takes many forms. Among the four thousand WPA employees there were laboratory technicians, physicians, nurses, researchers, investigators, clerical workers and miscellaneous help. "One of the most notable instances," Mr. Hunter continued, "is illustrated by the development of venereal disease control work in Chicago. Largely as the result of the assistance rendered by the Work Projects Administration, the Chicago Board of Health has been able to expand the capacity of its various venereal disease clinics from a daily average of five hundred patients in 1937 to about eighteen hundred today. This, according to preliminary evidence, has resulted in an actual decline in the prevalence of syphilis in Chicago." WPA has also participated in venereal disease control programs in New York, Boston and other cities.

First proposals for projects under the new nationwide program have already been received. One came from Dr. Roland R. Cross, Illinois state director of public health, and another from Dr. Herman N. Bundesen, president of the Chicago Board of Health.

MEDICAL RESEARCH COMMITTEE AND THE DEFENSE PROGRAM

President Roosevelt has designated four members of a medical research committee in the newly established Office of Scientific Research and Development to direct medical research in relation to the defense program, it was announced on July 17. They are Drs. Alphonse R. Dochez, professor of medicine, Columbia University College of Physicians and Surgeons, New York; Alfred N. Richards, professor of pharmacology and vice president for medical affairs of the University of Pennsylvania, Philadelphia; Lewis H. Weed, professor of anatomy, Johns Hopkins University School of Medicine, Baltimore, and chairman of the division of medical sciences of the National Research Council, and Albert Baird Hastings, Ph.D., Hamilton Kuhn professor of biologic chemistry, Harvard Medical School, Boston. The Office of Scientific Research and Development was established by an executive order of the President issued on June 30. Vannevar Bush, Ph.D., president of the Carnegie Institution of Washington, who has been chairman of the National Defense Research Committee, is now director of the new research agency.

U. S. ARMY TYPHOID VACCINE

The Army in the last fiscal year produced more typhoid vaccine at the Army Medical School, Washington, D. C., than in any other peacetime year. Not only are soldiers of the Army being inoculated against typhoid, but the vaccine is also being supplied to the United States Public Health Service, the Navy, the Civilian Conservation Corps, the Department of Justice, the Indian Service, the Veterans' Administration, the government of Puerto Rico and many others. As part of the good neighbor policy, the stock culture for vaccine has been furnished on request to other nations in the western hemisphere.

In the last year the output was increased more than eight times. A total of 33,500,000 cc., the equivalent of 8,500 gallons of typhoid vaccine, were made. This represents a saving to the government of \$1,540,000 over the cost of purchase. Typhoid

vaccine is being made by the Army with a culture from the body of a typhoid fever carrier in the Panama Canal Zone, who is kept under constant supervision by Army doctors. The original typhoid culture came from an English soldier who died in the Boer war, but recent investigation showed this strain had lost its potency. The cultures are preserved in glass tubes by a special process of freezing at a temperature of 108 degrees below zero and sealing in a partial vacuum. These tubes of cultures can be preserved for long periods.

The Army laboratory in which the vaccine is made is the largest of its kind in the world. Planting, harvesting and bottling of the vaccine are done in air conditioned cubicles which are sterilized by live steam prior to use. During all operations, filtered and sterilized air is pumped into the chambers and maintained at a pressure above that of the atmosphere in order to prevent the entrance of untreated air. The vaccine is standardized by the use of an "electric eye," so that all batches will be of the same strength. From a mixing chamber it passes to an automatic bottling device to be sealed in the final state for issue. Control tests are made on every run of vaccine at every stage of production. These tests extend over a period of four weeks, until which time no batch of vaccine is given a clearance for issue.

MEDICAL R. O. T. C. GRADUATES

More than four hundred R. O. T. C. students received certificates after completing the six weeks course July 23 at the Medical Field Service School, Carlisle Barracks, Pa. Seventeen medical schools east of the Mississippi were represented in this group, which was the first R. O. T. C. class to be graduated at Carlisle Barracks since the President declared the present military emergency. This brings the total of graduates, however, of the several camps and classes conducted at the Medical Field Service School to 18,546. Brig. Gen. Addison D. Davis, commandant of the school, presented the certificates. Col. Philip W. Huntington, George Washington University, Washington, D. C., was in immediate charge of the camp of the R. O. T. C. students, and his executive officer was Col. Asa M. Lehman, professor of military science and tactics at the Jefferson Medical College, Philadelphia. The other instructors at the camp besides the entire faculty of the Medical Field Service School comprises the professors of military science and tactics who have accompanied the R. O. T. C. students from their medical schools and include Lieut. Col. James H. Ashcraft, Boston University, Lieut. Col. Rowland D. Wolfe, Ohio State University, Major Harry G. Wyer, University of Vermont, Capt. Edward K. Reid, Syracuse University, Capt. John P. Cameron III, University of Pittsburgh, Capt. Dan. J. Bulmer, University of Michigan, and Lieut. James G. Kitchen II, University of Pennsylvania.

CHEMICAL WARFARE ARSENAL

The War Department announced on July 29 the contract for construction of a Chemical Warfare Service Arsenal at Huntsville, Ala., to cost about \$29,000,000. Units comprising the complete arsenal will include eleven manufacturing plants, four chemical loading plants, a depot, a plant storage, laboratories, shops, offices, a hospital, fire and guard installations, utilities and all necessary appurtenances. Located on a tract of more than 30,000 acres, which was selected for its proximity to fuel and raw materials for construction and manufacturing, the arsenal will produce smoke materials and other chemical warfare agents for the military establishment.

HUMAN HAIR IS NOT PURCHASED BY ARMY

The War Department announced on July 7 that human hair is not being purchased by the Army. This announcement was made because of many requests for information concerning the sale of human hair as the result of a wire service story that "blond human hair" was needed by the Army in the manufacture of certain instruments.

ARMY RESERVE OFFICERS ORDERED TO ACTIVE DUTY

FIRST CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, First Corps Area, which comprises the states of Maine, Vermont, New Hampshire, Rhode Island, Massachusetts and Connecticut:

ADAMS, Arthur J, 1st Lieut, Bridgeport, Conn, Camp Lee, Va
AIKEN, Sidney, Lieut, Manchester, Conn, Camp Lee, Va
BEGG, Charles F, 1st Lieut, Providence, R I, Camp Lee, Va
BERMAN, Leo, 1st Lieut, Boston, Camp Lee, Va
BLOSSOM, Frank O, Major, Caribou, Maine, Fort George C Meade, Md
BUNCE, James W, Major, North Adams, Mass, Fort Devens, Mass
BURKE, Francis H, 1st Lieut, Rockville, Conn, Camp Lee, Va
BURNS, Edward D, 1st Lieut, Arlington, Mass, Camp Lee, Va
DURGIN, Lawrence N, Captain, Amherst, Mass, Camp Edwards, Mass
DUZMATI, Paul P, 1st Lieut, Bridgeport, Conn, Camp Lee, Va
EASTMAN, Oliver R, 1st Lieut, Burlington, Vt, Fort Ethan Allen, Vt
FAMIGLIETTI, Joseph A, 1st Lieut, East Boston, Mass, Camp Lee, Va
FREEDMAN, Herman S, Lieut, Cambridge, Mass, Camp Lee, Va
GIFFORD, William H, 1st Lieut, Concord, N H, Camp Lee, Va
GOODMAN, Max, Lieut, Roxbury, Mass, Camp Lee, Va
HARASIMOWICZ, Paul P, Captain, Gardner, Mass, Camp Lee, Va
HEFFERNAN, Edward V, 1st Lieut, Providence, R I, Camp Lee, Va
JOHNSON, Elwood G, Lieut, Wilham, Mass, Fort Banks, Mass
KELLER, Jay E, 1st Lieut, Burlington, Vt, Camp Forrest, Tenn
LAWLESS, Thomas F, 1st Lieut, Stamford Conn, Camp Lee, Va
MCGREGOR, Eugene B, 1st Lieut, Lisbon, N H, Camp Lee, Va
MCINTYRE, George A, 1st Lieut, Montpelier, Vt, Camp Forrest, Tenn
MILLETT, Frank A, Major, Greenfield, Mass, Fort Adams, R I
MINIHAN, John C, 1st Lieut, Haverhill, Mass, Camp Edwards, Mass

MOULTON Charles W, 1st Lieut, Boston, Army Base, Boston
MUELLER, Harry L, 1st Lieut, Winchester, Mass, Camp Lee, Va
MULCAHY, Richard E, 1st Lieut, Wellesley, Mass, Camp Edwards, Mass
NEWCOMB, Richard V, 1st Lieut, Burlington, Vt, Fort Rodman, Mass
SHENKER, Benjamin M, 1st Lieut, Hartford, Conn, Fort Devens, Mass
SMITH, Hugh A, 1st Lieut, New Haven, Conn, Camp Lee, Va
WEBBER, Edward P, 1st Lieut, Winthrop, Maine, Fort Oglethorpe, Ga
YANKAUER, Alfred, Jr, 1st Lieut, Boston, Fort Bragg, N C

Orders Revoked

BEGG, Charles F, Lieut, Providence, R I
FEINMAN, Maxwell H, 1st Lieut, Lynn, Mass
HEFFERNAN, Edward V, Lieut, Providence, R I
MCINTYRE, George A, Lieut, Montpelier, Vt
MONGILLO, Frank, Major, New Haven, Conn
MUELLER, Harry L, Lieut, Winchester, Mass
NILES, John O, 1st Lieut, Osterville, Mass
RUBENSTEIN, Abraham D, 1st Lieut, Brighton, Mass
SPIEGEL, Charles M, 1st Lieut, New Haven, Conn
WITTIG, Joseph E, Lieut, West Warwick, R I

CORRECTION

Lieutenant Geller on Active Duty.—In THE JOURNAL, July 5, page 46, under the First Corps Area, the name of 1st Lieut Philip S Geller, Newport, R I, was included among the orders revoked. Since his previous orders were revoked, Lieutenant Geller has again been ordered to active duty and is now serving at Fort Adams, R I

THIRD CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Third Corps Area, which comprises the states of Pennsylvania, Virginia, District of Columbia and Maryland:

BEAVERS, Charles Lee, 1st Lieut, Franklin, Va, Camp Grant, Ill
BERRY, Lorenzo Robert, Captain, Washington, D C, Fort Dix, N J
BLOCK, Louis Henry, 1st Lieut, Philadelphia, Camp Pendleton, Va
BYERS, John Maxwell, 1st Lieut, Hyattsville, Md, Camp Lee, Va
CAPLAN, Milton Louis, 1st Lieut, Ellwood City, Pa, Fort Belvoir, Va
COCHRAN, James Edward, 1st Lieut, Pittsburgh, Camp Lee, Va
CORRADO, Albert Guv, 1st Lieut, Pittsburgh, Indiantown Gap Military Reservation, Pa
DANISH, Jacob Mayr, 1st Lieut, Washington, D C, Camp Lee, Va
DEPROPHETIS, Nino, 1st Lieut, Chester, Pa, Camp Lee, Va
DIERWECHTER, Reuben James, 1st Lieut, Philadelphia, Camp Lee, Va
DORNENBURG, James Raymond, 1st Lieut, Carnegie, Pa, Camp Lee, Va
DOWNEY, Regis Tallon, 1st Lieut, Greensboro, Pa, Camp Lee, Va
EDDINGER, Leo Clement, 1st Lieut, Allentown, Pa, Camp Lee, Va
ELLIOTT, Israel Edward, Jr, 1st Lieut, Washington, D C, Fort Dix, N J
ERHARD, Gerald Arthur, 1st Lieut, Curwensville, Pa, Camp Lee, Va
ERVIN, Kenneth Dubois, 1st Lieut, Jenkintown, Pa, Camp Lee, Va
FORSTER, Hans Walter, Jr, 1st Lieut, Philadelphia, Camp Lee, Va
FREEDMAN, Abraham G, 1st Lieut, Philadelphia, Camp Lee, Va
FREEDMAN, Donald Kenneth, 1st Lieut, Washington, D C, Camp Grant, Ill
GARNER, Blune Rosenberger, 1st Lieut, Doylestown, Pa, Indiantown Gap Military Reservation, Pa
GASSAWAY, William Farrow, 1st Lieut, Ellicott City, Howard County, Md, Camp Lee, Va
GAYER, Leo Junior, 1st Lieut, Meyersville, Frederick County, Md, Camp Lee, Va
GILLIGAN, Frank Patrick, 1st Lieut, Ashley, Pa, Camp Lee, Va
GREENWOOD, George Roy, 1st Lieut, Sugar Notch, Pa, Camp Lee, Va
GREM, Francis Matthew, 1st Lieut, Philadelphia, Camp Lee, Va
GRIMES, James Thomas, 1st Lieut, Philadelphia, Camp Lee, Va
HAINES, Risley Trith, 1st Lieut, Baltimore, Fort George G Meade, Md
HAMDI, Turgut Nazif, 1st Lieut, Bryn Mawr, Pa, Camp Lee, Va
HOFFMAN, Frank David, 1st Lieut, Greensburg, Pa, Camp Lee, Va
HOLMBOE, Harris Studley, 1st Lieut, Charlottesville, Va, Camp Lee, Va
HOLT, Frederick Guy, 1st Lieut, Shamokin, Pa, Camp Lee, Va
HOON, James Richard, 1st Lieut, Monongahela, Pa, Camp Lee, Va
HURST, John Witmer, 1st Lieut, Altoona, Pa, Camp Lee, Va
IRWIN, Ralph Theodore, 1st Lieut, Lancaster, Pa, Camp Lee, Va
KACZYNSKI, Stanley Bernard, 1st Lieut, Pittsburgh, Holabird Quartermaster Depot, Baltimore
KAY, Alvin Irving, 1st Lieut, Washington, D C, Camp Lee, Va

KELLER, David Henry, Lieut Col, Stroudsburg, Pa, Camp Lee, Va
KELLY, Vernon Charles, 1st Lieut, Baltimore, Camp Lee, Va
KISTLER, William Stephen, 1st Lieut, Pennsburg, Pa, Camp Pendleton, Va
KLINE, Jacob Maurice, 1st Lieut, Ligonier, Pa, Camp Lee, Va
KNOWLES, Willard Edward, 1st Lieut, Philadelphia, Camp Lee, Va
KOSTYAL, John Louis, 1st Lieut, Pittsburgh, Camp Lee, Va
LANDIS, Lloyd Mervin, 1st Lieut, Lancaster, Pa, Camp Lee, Va
LARGE, Fred Denzel, 1st Lieut, Clairton, Va, Camp Lee, Va
LAURIA, Michael Herbert, 1st Lieut, Philadelphia, Camp Lee, Va
LEEBORN, William M, 1st Lieut, Philadelphia, Camp Lee, Va
LEWIS, Homer Hill, Jr, 1st Lieut, Clearfield, Pa, Camp Lee, Va
LYON, William Cochran, 1st Lieut, Ardmore, Pa, Camp Lee, Va
MAHER, Robert Campbell, 1st Lieut, Leechburg, Pa, Camp Lee, Va
MARTIN, Frederick Herman, 1st Lieut, Macungie, Pa, Camp Grant, Ill
McCORMICK, Richard Harry, 1st Lieut, Emsworth, Pa, Camp Grant, Ill
McCUNE, David Pollock, Jr, 1st Lieut, McKeesport, Pa, Camp Lee, Va
McGOVERN, William Joseph, 1st Lieut, Woodville, Pa, Camp Grant, Ill
MENSCH, Maurice, 1st Lieut, Washington, D C, Camp Lee, Va
MILNAMOW, Paul Thomas, 1st Lieut, Wilkes Barre, Pa, Camp Grant, Ill
MUNCHAK, Alexander Michael, 1st Lieut, Scranton, Pa, Camp Lee, Va
NADLER, Manuel Princeton, 1st Lieut, Ambridge, Pa, Camp Lee, Va
OGLESBY, Forrest Elliott, 1st Lieut, Oceana, Va, Camp Lee, Va
PILGRAM, Robert Hark, 1st Lieut, Lancaster, Pa, Camp Grant, Ill
ROMAINE, Hunter Huidekoper, 1st Lieut, Petersburg, Va, Camp Lee, Va
ROSEN, Harold G, 1st Lieut, Philadelphia, Camp Davis, N C
SAVAGE, Lester Wells, 1st Lieut, Philadelphia, Fort George G Meade, Md
SAYLOR, Blair Willard, 1st Lieut, Rockwood, Pa, Camp Grant, Ill
SCHAAF, Charles Francis, 1st Lieut, Erie, Pa, Camp Grant, Ill
SCHEIN, Robert Alexander, 1st Lieut, Homestead, Pa, Camp Grant, Ill
SCHINDLER, Blune Markwood, 1st Lieut, Cumberland, Md, Indiantown Gap Military Reservation, Pa
SCHINFELD, Louis Harry, 1st Lieut, Philadelphia, Camp Grant, Ill
SCOTT, Robert James, 1st Lieut, Onancock, Va, Camp Grant, Ill
SHAFFER, John Francis Regis, 1st Lieut, Pittsburgh, Camp Grant, Ill
SHARPS, Frank, 1st Lieut, Philadelphia, Camp Grant, Ill
SHENKIN, Henry Arnold, 1st Lieut, Philadelphia, Camp Grant, Ill
SILVERSTINE, Leshe Byron, 1st Lieut, Bradford, Pa, Camp Grant, Ill
SINGLETON, Albert Olin, Jr, 1st Lieut, Philadelphia, Camp Grant, Ill
STEELE, Ralph Edward, 1st Lieut, Carlisle, Pa, Indiantown Gap Military Reservation, Pa
STEINBERG, Edgar Irwin, 1st Lieut, Philadelphia, Camp Grant, Ill
STUTCH, Reuben, 1st Lieut, Pittsburgh, Camp Grant, Ill
TUFT, Harold Seymour, 1st Lieut, Philadelphia, Camp Grant, Ill
VILSACK, George Ray, 1st Lieut, Pittsburgh, Camp Grant, Ill

VOLLMER, Donald Henry, 1st Lieut, Takoma Park, Md, Camp Lee, Va
 WARSHAFSKY, Morton, 1st Lieut, Philadelphia, Camp Grant, Ill
 WEDDELL, James Russell, 1st Lieut, Elizabeth, Pa, Camp Lee, Va
 WELSH, Albert Eugene, Jr, 1st Lieut, Philadelphia, Camp Grant, Ill

WHILDIN, James Griffith, 1st Lieut, Lansford, Pa, General Dispensary, U S Army, Baltimore
 WILCOX, Homer Bowen, Jr, 1st Lieut, Kingston, Pa, Camp Lee, Va
 ZULICH, Philip Diefenderfer, 1st Lieut, Orwigsburg, Pa, Camp Lee, Va

Orders Revoked

ABRAMOVITZ, Leonard J, 1st Lieut, Baltimore
 CANADA, Charles C, 1st Lieut, Arlington, Va
 DANISH, Jacob Mayr, 1st Lieut, Washington, D C
 DUFAULT, Leo W, 1st Lieut, Washington, D C
 FEAR, Jesse G, 1st Lieut, Berwick, Pa
 GILMARTIN, Joseph A, Captain, Pittsburgh
 GRAY, Raymond J, Captain, Pittsburgh
 GREEN, Manuel E, Captain, Pittsburgh
 HARBOLD, Harold Valentine, 1st Lieut, York, Pa
 HEIMBACH, James A, Major, Altoona, Pa
 HOFFMAN, Franklin David, 1st Lieut, Greensburg, Pa
 JONES, Lawrence Paul, Captain, Emporia, Va
 KILLIUS, William J, 1st Lieut, Johnstown, Pa
 KITCHELL, James R, Captain, Bala Cynwyd, Pa

FOURTH CORPS AREA

The following additional medical reserve corps officers have been ordered to active duty by the Commanding General, Fourth Corps Area, which comprises the states of Tennessee, North Carolina, South Carolina, Alabama, Georgia, Mississippi, Florida and Louisiana:

ADAMS, Everett H, 1st Lieut, Rutledge, Ga, Camp Grant, Ill
 ANDERSON, William H, Jr, 1st Lieut, Atlanta, Ga, Fort Bragg, N C
 ANDERSON, William O, 1st Lieut, Alabama City, Ala, Camp Grant, Ill
 BARKSDALE, Irving S, Captain, Greenville, S C, Fort Bragg, N C
 BOAZ, Thurmond D, Jr, 1st Lieut, Shreveport, La, Fort Benning, Ga
 BOLAND, Joseph H, Captain, Atlanta, Ga, Camp Shelby, Miss
 BLACK, Irby Harry, 1st Lieut, Live Oak, Fla, Camp Shelby, Miss
 BLUM, Joseph E, Jr, 1st Lieut, Greenwell Springs, La, Camp Claiborne, La
 BREATH, Marshall Burt, 1st Lieut, New Orleans, Fort Bragg, N C
 BROWN, Richard K, 1st Lieut, Greenville, S C, Camp Davis, N C
 DAVIDGE, Lucious Lamar, 1st Lieut, Shreveport, La, Camp Wheeler, Ga
 DAVIS, Frank M, 1st Lieut, Corinth, Miss, Camp Livingston, La
 DOLAN, Thomas R, 1st Lieut, New Orleans, Camp Claiborne, La
 DONATHAN, Earl Raymond, 1st Lieut, Etowah, Tenn, Fort Bragg, N C
 ERWIN, J W, 1st Lieut, Blountville, Tenn, Camp Claiborne, La
 EVANS, Ira C, 1st Lieut, Charleston, S C, Camp Claiborne, La
 EVANS, Kenneth P, 1st Lieut, Sylacauga, Ala, Fort Oglethorpe, Ga
 FARMER, Joseph Arthur, 1st Lieut, Shelby, N C, Fort McClellan, Ala
 FERGUSON, William H, Captain, Memphis, Tenn, Fort Bragg, N C
 GAGHET, Fred S, 1st Lieut, Lakeland, Fla, Camp Blinding, Fla
 GESSLER, Carl N, 1st Lieut, McMinville, Tenn, Fort Benning, Ga
 GLEASON, Albert H, 1st Lieut, Umatilla, Fla, Fort Benning, Ga
 GREEN, Gordon L, 1st Lieut, Rome, Ga, McDill Field, Fla
 GROVE, Edward W, Captain, Gainesville, Ga, Camp Claiborne, La
 HANKS, James Monroe, 1st Lieut, Anderson, S C, Fort Bragg, N C
 HARGIS, Albert S, Jr, 1st Lieut, Birmingham, Ala, Camp Claiborne, La
 HENSON, Thomas A, 1st Lieut, Walstonburg, N C, Fort Benning, Ga
 HERD, Leslie Phillips, Major, Elizabethton, Tenn, Camp Stewart, Ga
 HICKMAN, Walter B, 1st Lieut, Louisville, Miss, Camp Claiborne, La
 HUDSON, Harry H, 1st Lieut, Cleveland, Tenn, Camp Livingston, La
 HUEY, Thomas Ford, Jr, 1st Lieut, Anniston, Ala, Camp Stewart, Ga
 JACOBS, Sydney, Captain, New Orleans, Camp Shelby, Miss
 JACKSON, James T, 1st Lieut, Montgomery, Ala, Fort Bragg, N C
 JENKINS, Harry H, Captain, Knoxville, Tenn, Fort Oglethorpe, Ga
 JONES, Clyde T, 1st Lieut, West Jefferson, N C, Camp Davis, N C
 KINBERGER, Frank R, 1st Lieut, New Orleans, Fort Jackson, S C
 LACEY, William H, 1st Lieut, Georgetown, S C, Camp Davis, N C
 LEVY, Morton Lee, 1st Lieut, Jonesville, La, Camp Polk, La
 LITTLE, Tom French, 1st Lieut, Tifton, Ga, Fort Benning, Ga
 LOVETT, Raymond E, 1st Lieut, New Orleans, Camp Davis, N C
 LOWRY, Harvey M, 1st Lieut, Memphis, Tenn, Fort Benning, Ga

LUCIDO, Joseph L, 1st Lieut, Elkin, N C, Fort Jackson, S C
 McCALL, Charles S, Jr, 1st Lieut, Bennettsville, S C, Fort Benning, Ga
 McPEAKE, William T, Jr, 1st Lieut, Morris Chapel, Tenn, Fort Benning, Ga
 MILLER, Samuel E, Captain, State Park, S C, Camp Shelby, Miss
 MORTON, John Buck, 1st Lieut, Gray, Ga, Camp Wheeler, Ga
 MUSARRA, Elmer A, 1st Lieut, Marietta, Ga, Fort McPherson, Ga
 NAVE, Dick Donnelly, 1st Lieut, Mountain City, Tenn, Fort Barrancas, Fla
 NEUKOM, George B, 1st Lieut, New Albany, Miss, Fort Benning, Ga
 NEWTON, Isaac James, 1st Lieut, Nashville, Tenn, Camp Wheeler, Ga
 OLIVER, Benjamin M, Jr, 1st Lieut, State Park, S C, Fort McClellan, Ala
 OWINGS, Francis P, 1st Lieut, Union, S C, Camp Shelby, Miss
 PALIK, Emil Emery, 1st Lieut, New Orleans, Camp Shelby, Miss
 ROBBINS, Bernard L, 1st Lieut, Miami Beach, Fla, Fort Benning, Ga
 ROBINSON, William J, 1st Lieut, Matthews, S C, Fort Bragg, N C
 ROPER, C James, 1st Lieut, Jasper, Ga, Fort Benning, Ga
 SCHNEIDER, Meyer M, 1st Lieut, Savannah, Ga, Camp Blanding, Fla
 SEAY, Hillis L, Captain, Huntersville, N C, Camp Shelby, Miss
 SHERER, Raymond J, 1st Lieut, Jasper, Ala, Camp Wheeler, Ga
 SHURE, Irving Isadore, 1st Lieut, Bethel, N C, Camp Polk, La
 SMITH, Leo, 1st Lieut, Weyeross, Ga, Fort Jackson, S C
 SODEMAN, William A, 1st Lieut, New Orleans, Camp Wheeler, Ga
 SOSKIS, Elbert Joque, 1st Lieut, Mulberry, Fla, Fort Benning, Ga
 SWISHER, Otto Jay, 1st Lieut, Covington, Tenn, Camp Blinding, Fla
 THOMAS, Ford A, Captain, Urania, La, Camp Claiborne, La
 THOMAS, John Henry, 1st Lieut, Gainesville, Fla, Camp Stewart, Ga
 THOMPSON, Charles C, Jr, 1st Lieut, Columbia, Miss, Fort Moultrie, S C
 TRAPP, Walter Russell, 1st Lieut, Tusculumbia, Ala, Camp Forrest, Tenn
 TURNER, James Dormon, 1st Lieut, Winstboro, S C, Fort Jackson, S C
 VARNER, Claude F, 1st Lieut, Memphis, Tenn, Camp Shelby, Miss
 VON WERSOWETZ, Odon F W, 1st Lieut, Chattanooga, Tenn, Camp Blanding, Fla
 WALLIS, Thomas H, 1st Lieut, Ocala, Fla, Fort McPherson, Ga
 WATSON, Francis M, 1st Lieut, Chipley, Fla, Quartermaster's Depot, New Orleans
 WILKINS, William B, 1st Lieut, West Palm Beach, Fla, Camp Wheeler, Ga
 WILEY, Felix J, Jr, 1st Lieut, New Orleans, Fort Bragg, N C
 WILLIAMS, Harvey McL, 1st Lieut, Aberdeen, Miss, Camp Wheeler, Ga
 WILSON, Isaac R, Jr, 1st Lieut, Charleston, S C, Camp Davis, N C
 WEINSTEIN, Albert, Major, Nashville, Tenn, Fort Oglethorpe, Ga
 WEINSTEIN, Bernard M, Captain, Nashville, Tenn, Camp Livingston, La
 WESTERFIELD, Charles W, 1st Lieut, Augusta, Ga, Camp Livingston, La
 WOOD, Charles S, 1st Lieut, New Orleans, Fort Barrancas, Fla
 WOODS, Harold Vernon, 1st Lieut, Nashville, Tenn, Fort Jackson, S C

Orders Revoked

BAUGH, Wendell P, Major, Decatur, Ala
 BOLAND, Joseph H, Captain, Atlanta, Ga
 BOOTH, Thomas Eugene, 1st Lieut, Montgomery, Ala
 BROWN, Randall Gay, 1st Lieut, Graymont, Ga
 CLARK, Arthur Lee, 1st Lieut, Iowa, La
 COX, Marcus Edward, 1st Lieut, Charleston, S C
 COYLE, Daniel Joseph, Captain, Birmingham, Ala
 EHLERT, William E, 1st Lieut, New Orleans
 GORMAN, John M, Major, Jacksonville, Fla
 HAIK, George M, 1st Lieut, New Orleans
 HILLARD, Irving R, 1st Lieut, Jackson, Tenn
 IMERMANN, Harold M, 1st Lieut, 6th Corps Area
 JACKSON, James T, 1st Lieut, Montgomery, Ala
 JACOBS, Sydney, Captain, New Orleans
 JENKINS, Hughes B, Major, Donaldsonville, Ga
 JERNIGAN, Sterling H, 1st Lieut, Atlanta, Ga
 KELLEY, Oscar Lee, 1st Lieut, Raiford, Fla

KLUGH, George F, Jr, 1st Lieut, Atlanta, Ga

 NEUKOM, George B, 1st Lieut, New Albany, Miss
 PALIK, Emil Emery, 1st Lieut, New Orleans
 PHILLIPS, Herbert S, 1st Lieut, Holly Springs, Miss
 PREVO, Samuel B, 1st Lieut, Memphis, Tenn
 ROYALS, James Lee, 1st Lieut, Meridian, Miss
 SCHAPIRO, Mark Meyer, 1st Lieut, Birmingham, Ala
 SODEMAN, William A, 1st Lieut, New Orleans
 WALKER, Richard H, Jr, Captain, Orlando, Fla
 WILSON, Isaac R, Jr, 1st Lieut, Charleston, S C
 WOOD, Frank Alton, Captain, Monroe, La
 WORLEY, James Harr, 1st Lieut, Asheville, N C

FIFTH CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Fifth Corps Area, which comprises the states of Ohio, West Virginia, Indiana and Kentucky:

ALBERT, Irwin C, 1st Lieut, Cincinnati, Fort Thomas, Ky
ALLENBACH, Theodore C, Captain, Columbus, Ohio, Fort Hayes, Ohio
ARMSTRONG, Charles B, 1st Lieut, Cincinnati, Fort Hayes, Ohio
BENNETT, Willard D, 1st Lieut, Lexington, Ky, Bowman Field, Ky
BLASSER, Seymour, 1st Lieut, Outwood, Ky, Bowman Field, Ky
CRONE, John T, Jr, 1st Lieut, Milford, Ohio, Fort Knox, Ky
DAVIDOW, Sidney L, 1st Lieut, North Jackson, Ohio, Air Base, Fort Wayne, Ind
DAVIS, Howell J, Captain, Owensboro, Ky, Bowman Field, Ky
DAVIS, Samuel G, 1st Lieut, Brazil, Ind, Bowman Field, Ky
DEOREO, Gerard A, 1st Lieut, Cleveland Heights, Ohio, Fort Thomas, Ky
DOWNING, Robert E, 1st Lieut, Lexington, Ky, Bowman Field, Ky
DULIN, Basil B, 1st Lieut, Bedford, Ind, Fort Hayes, Ohio
FANELLI, Walter, Captain, Cleveland, Camp Forrest, Tenn
FRIELICH, Myron A, 1st Lieut, Zanesville, Ohio, Baer Field, Fort Wayne, Ind
HARPER, EDWARD O, Major, East Cleveland, Ohio, Fort George G Meade, Md
HAUSS, John T, 1st Lieut, Celina, Ohio, Air Base, Charlotte, N C
HERBST, Mark G, 1st Lieut, Canton, Ohio, Fort Hayes, Ohio
HICKMAN, Archibald L, Jr, 1st Lieut, Hammond, Ind, Camp Grant, Ill
HOLMBERG, Robert E, 1st Lieut, Cleveland, Fort Wayne Air Base, Fort Wayne, Ind

SIXTH CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Sixth Corps Area, which comprises the states of Wisconsin, Illinois and Michigan:

ADAMS, Vail B, 1st Lieut, Evanston, Ill, Air Base, Tucson, Ariz
AHLG, Charles E, 1st Lieut, Chicago, Medical Replacement Training Center, Camp Grant, Ill
BAUER, Benedict J, 1st Lieut, Detroit, 30th Division, Fort Jackson, S C
BERGSTROM, Paul L, 1st Lieut, Kirkland, Ill, 29th Division, Fort Meade, Md
BERMAN, Benjamin B, 1st Lieut, East St Louis, Ill, 33d Division, Camp Forrest, Tenn
BORNSTEIN, John S, 1st Lieut, Chicago, Station Complement, Camp Wheeler, Ga
BRAUDE, Abraham I, 1st Lieut, Chicago, 29th Division, Fort Meade, Md
BRODSKY, Abraham, 1st Lieut, Manteno, Ill, 9th Station Hospital, Fort McClellan, Ala
BUNCHMAN, Lester P, 1st Lieut, Clinton, Ill, 33d Division, Camp Forrest, Tenn
CAMERON, Wayne T, 1st Lieut, Evanston, Ill, 119th Field Artillery, Fort Leonard Wood, Mo
CHERNER, Abraham M, 1st Lieut, Chicago, 10th Station Hospital, Camp Claiborne, La
CHRISTIANSON, Oscar O, Captain, Peoria, Ill, 1,608th Corps Area Service Unit (Medical Section), Camp Grant, Ill
CLIFFORD, Robert P, 1st Lieut, Detroit, 177th Field Artillery, Fort Leonard Wood, Mo
CONLEY, Raymond H, 1st Lieut, Chicago, Medical Replacement Training Center, Camp Grant, Ill
DOUGHERTY, Roderick J, 1st Lieut, Chicago, 33d Division, Camp Forrest, Tenn
EMANUELL, Nicola V, 1st Lieut, Chicago, Station Complement, Camp Davis, N C
FEINBERG, Milton, 1st Lieut, Chicago, 191st Tank Battalion, General Headquarters Reserve National Guard, Fort Meade, Md
FELDMAN, Abraham W, 1st Lieut, Chicago, 33d Division, Camp Forrest, Tenn
FLEMING, James T, 1st Lieut, Chicago, 10th Station Hospital, Camp Claiborne, La
FRIEDMAN, Jack, 1st Lieut, Chicago, Station Complement, Camp Polk, La
GOLLIN, Frank F, 1st Lieut, LaFarge, Wis, 119th Field Artillery, Fort Leonard Wood, Mo

Orders Revoked

ALLISON, Olaf W, 1st Lieut, Danville, Ill, 27th Division, Fort McClellan, Ala
BUCKLEY, Clarence H, Captain, Menomonee, Wis, 10th Station Hospital, Camp Claiborne, La
CRANE, Wesley T, 1st Lieut, Northbrook, Ill
HILL, Edward L, 1st Lieut, Jacksonville, Ill
HURBLF, William F, Jr, 1st Lieut, Decatur, Ill
JANA, Joseph T, 1st Lieut, Berwyn, Ill, 29th Division, Fort Meade, Md
JANSON, Carl H, 1st Lieut, Homewood, Ill, 33d Division, Camp Forrest, Tenn
LARRABEE, Walter F, Jr, 1st Lieut, Chippewa Falls, Wis, Station Complement, Camp Wheeler, Ga
McRAE, Louis A, 1st Lieut, Houston, Texas, 135th Medical Regiment, Camp Shelby, Miss

HUNTER, Shelton B, Jr, 1st Lieut, Lexington, Ky, Bowman Field, Ky
JOHNSTON, Robert L, Captain, Silverton, Ohio, Fort Leonard Wood, Mo
KENNEDY, Julian C, 1st Lieut, Indianapolis, Bowman Field, Ky
KESSLER, Morris M, 1st Lieut, Cleveland Heights, Ohio, Fort Hayes, Ohio
KING, George L, Captain, Alliance, Ohio, Fort George G Meade, Md
KISTLER, Victor N, 1st Lieut, Columbus, Ohio, Fort Wayne, Ind
MARREN, John J, Captain, Lexington, Ky, Fort Knox, Ky
MECKSTROTH, Paul G, 1st Lieut, New Knoxville, Ohio, Fort McClellan, Ala
MILLER, Roland E, 1st Lieut, Plymouth, Ind, Fort Leonard Wood, Mo
MISHLER, Howard V, 1st Lieut, Cleveland, Fort Knox, Ky
NEARY, Edward P, Captain, Cleveland Heights, Ohio, Fort Knox, Ky
NEFF, Frank R, Captain, London, Ohio, Fort Wayne, Ind
PHINNEY, James D, 1st Lieut, Cincinnati, Kelly Field, Texas
REEDER, Henry H, Captain, Jeffersonville, Ind, Fort Knox, Ky
ROSSMAN, Philip L, 1st Lieut, Cleveland, Fort Wayne, Ind
ROTMAN, Harry G, 1st Lieut, Jasonville, Ind, Fort Knox, Ky
SAUER, Richard T, 1st Lieut, Dayton, Ohio, Fort Knox, Ky
SISEK, Henry, 1st Lieut, Youngstown, Ohio, Fort Hayes, Ohio
SMYERS, Webster C, 1st Lieut, Dayton, Ohio, Fort Hayes, Ohio
STOLL, William A, 1st Lieut, Louisville, Ky, Camp Shelby, Miss
STRAUSS, Victor M B, 1st Lieut, Cincinnati, Fort Wayne, Ind
VAN HORN, Earl C, 1st Lieut, Springfield, Ohio, Fort Knox, Ky
VOTYPKA, Edward A, 1st Lieut, Cleveland, Fort Knox, Ky
VOTYPKA, Joseph A, 1st Lieut, Cleveland, Fort Knox, Ky
WEBB, Jack G, 1st Lieut, Louisville, Ky, Camp Shelby, Miss
WEBB, William M, 1st Lieut, Indianapolis, Bowman Field, Ky
WEISS, Morris, 1st Lieut, Cleveland, Fort Knox, Ky
ZEITHAML, Carl E, 1st Lieut, Cleveland, Fort Wayne, Ind

HOLDEN, David, Lieut Colonel, Chicago, 182d Field Artillery, Fort Leonard Wood, Mo
HORODKO, Edward J, 1st Lieut, Chicago, 33d Division, Camp Forrest, Tenn
HOYT, Arthur W, 1st Lieut, Battle Creek, Mich, 182d Field Artillery, Fort Leonard Wood, Mo
JONES, Robert R, 1st Lieut, Coal Valley, Ill, 33d Division, Camp Forrest, Tenn
KARRAS, Samuel J, 1st Lieut, Melrose Park, Ill, 30th Division, Fort Jackson, S C
LAM, Francis Lee, 1st Lieut, Battle Creek, Mich, 33d Division, Camp Forrest, Tenn
LAMPERT, Elmer G, 1st Lieut, Wheaton, Ill, Armored Force Troop Unit, Fort Benning, Ga
LEMBERG, Louis, 1st Lieut, Chicago, 177th Field Artillery, Fort Leonard Wood, Mo
LOISELLE, Albert O, 1st Lieut, Chicago, Station Hospital, Fort Sam Houston, Texas
LORITZ, Anthony T, 1st Lieut, Chicago, 207th General Hospital, Camp Livingston, La
LOSEFF, Samuel A, 1st Lieut, Chicago, 33d Division, Camp Forrest, Tenn
MARESH, Everett R, 1st Lieut, Detroit, 33d Division, Camp Forrest, Tenn
NEWELL, Robert H, 1st Lieut, Oak Park, Ill, Scott Field, Ill
OBERHILL, Harold R, 1st Lieut, Chicago, 135th Medical Regiment, Camp Shelby, Miss
OTTENSTEIN, Harold H, 1st Lieut, Milwaukee, Replacement Center Infirmary, Camp Grant, Ill
PERKINS, Robert D, 1st Lieut, Moline, Ill, 106th Cavalry, Camp Livingston, La
RANNEY, Alden B, 1st Lieut, Oak Park, Ill, 33d Division, Camp Forrest, Tenn
SCOTT, Wilbert E, Jr, 1st Lieut, Chicago, Medical Replacement Training Center, Camp Grant, Ill
STANLEY, Sherburn M, 1st Lieut, Detroit, 177th Field Artillery, Fort Leonard Wood, Mo
WAGLEY, Perry V, Captain, Pontiac, Mich, U S Army Induction Station, Milwaukee
WALGER, William D, 1st Lieut, Ashley, Ill, 135th Medical Regiment, Camp Shelby, Miss
WESCOTT, Royal J, 1st Lieut, Marquette, Mich, 182d Field Artillery, Fort Leonard Wood, Mo
WASSERMAN, Reuben R, 1st Lieut, Chicago, 27th Division, Fort McClellan, Ala
WILLIAMS, William R, 1st Lieut, Riverside, Ill, Station Complement, Camp Davis, N C

MALOOF, George J, 1st Lieut, Madison, Wis, 135th Medical Regiment, Camp Shelby, Miss
MAXWELL, James H, 1st Lieut, Detroit
PFETTER, Isidore S, 1st Lieut, Elmhurst, Mich, 33d Division, Camp Forrest, Tenn
RICHARDS, Ned W, 1st Lieut, Saginaw, Mich, Station Complement, Camp Davis, N C
ROSEN, Benjamin B, 1st Lieut, Chicago
ROYCE, Grant E, 1st Lieut, Harvard, Ill, U S Army Induction Station, Milwaukee
SLAYBAUGH, James C, Captain, Milwaukee
WEIDNER, Morris R, 1st Lieut, Dolton, Ill
WILLIAMS, William R, 1st Lieut, Riverside, Ill

ORGANIZATION SECTION

MEDICAL LEGISLATION

DISTRICT OF COLUMBIA

Changes in Status.—H. R. 4599 has passed the House and has been reported to the Senate, authorizing the Federal Security Administrator to accept gifts for St. Elizabeths Hospital and to provide for the administration of such gifts. H. R. 4660 has passed the House and has been reported to the Senate, amending an act providing aid to needy blind persons of the District of Columbia by authorizing the expenditure of funds for necessary burial expenses of such persons who while living were receiving aid under the act. H. R. 4498 has passed the House and is pending in the Senate with a favorable

committee report, authorizing the Federal Security Administrator to admit to St. Elizabeths Hospital in the District of Columbia, for treatment, certain officers, clerks and employees in the foreign service who have been legally adjudged insane in any foreign country and with respect to whom it has been impossible to establish a legal residence in one of the states, territories or the District of Columbia. The bill provides that at the request of any such patient, his relatives or friends, a hearing shall be held in the District Court of the United States for the District of Columbia on his mental condition and on the right of the superintendent of St. Elizabeths Hospital to hold him for treatment.

MEDICAL ECONOMIC ABSTRACTS

NEW LOW DEATH RATE

According to the statisticians of the Metropolitan Life Insurance Company the 1941 January-June mortality experience of the company's industrial policyholders set a new low death rate record of 8 per thousand for the first six months of 1941. From present indications it seems likely that the rate for the full year will be among the lowest in the company's history.

Among the respiratory diseases, pneumonia mortality for the first six months of this year declined 13.2 per cent below the rate for the corresponding period of 1940, while the tuberculosis rate of 44.8 per hundred thousand is the lowest of any January-June period.

One of the most "satisfactory" features of the 1941 half year record is the continued decline in maternal mortality, for which the death rate this year was slightly lower than in 1940 and only a little more than half that of 1935. And this was in spite of the fact that the marriage rate is up and the number of births has increased materially.

The statisticians declare that the "only really disturbing element in the mortality record for the first half of 1941 is the high incidence of fatal accidents, particularly motor vehicle accidents, mortality from which was 26.1 per cent higher than in the corresponding period of 1940.

THE INDUSTRIAL MEDICAL SERVICE OF THE STANDARD OIL COMPANY OF NEW JERSEY AND AFFIL- IATED COMPANIES

Neglect of employee absenteeism from preventable sickness or accident is not regarded as sound business by many large corporations. The widespread activities of the 23 year old medical department of the Standard Oil Company of New Jersey exemplify to what extent preventive industrial medicine has been accepted as indispensable by enlightened management.¹ The company operates in the United States, Europe, the East and West Indies and South America. It requires medical personnel and facilities, as indicated in table 1.

The services of medical examiners who operate on a fee basis are needed mainly to investigate the physical qualifications of candidates for employment in areas where concentrations of employees are insufficient to justify the appointment of full time physicians and to provide for direct medical or surgical service for industrial accidents or occupational disease. In the tropics thirty-two hospitals are maintained to accommodate the medical, surgical and obstetric requirements of employees and their

families. Elsewhere employees must consult their own family physicians for any form of treatment. Altogether this industrial medical service touches in some manner the physical welfare of 186,344 people engaged in the production, transportation and sale of petroleum products.

TABLE 1.—Medical and Other Facilities

Full time physicians.....	109
Part time physicians.....	23
Dentists.....	2
Registered nurses.....	101
Other medical personnel.....	400
Medical examiners (fee basis).....	1,010
Hospitals.....	32
Hospital beds.....	1,011

Under this system an administrative formula has been developed which works well in any location. Local adjustments are necessary to meet the requirements of climate, terrain, racial strains, unusual working conditions or specific occupational exposures. As in all soundly conducted industrial medical departments, principal reliance rests on placement and periodic health examinations, prophylaxis, sanitation, and the maintenance and proper interpretation of medical records and statistics. From its own statement, the company bases its evaluation of medical trends and results on every case of lost time disability lasting one or more calendar days. This is a rare and increasingly valuable depository of clinical information. The regular analysis of these records ought to be made widely available to the general profession as well as to industrial physicians. The company statisticians have determined that the average days of disability for each one of their own employees

TABLE 2.—Frequency of Sickness and Injuries

	Frequency Rates per 1,000 Employees Per Annum					
	Number of Employees	Total	Sick-ness	Non-Indus-trial In-juries	Indus-trial In-juries	Non-ef-fective Rates
United States...	30,515	574.02	543.21	22.20	9.15	17.29
Europe.....	3,924	333.51	295.26	18.60	19.83	14.81
Tropics.....	37,083	479.03	412.00	22.62	47.47	11.59
Total.....	71,522	512.14	462.45	22.22	27.47	14.21

in the United States is six and thirty-one one-hundredths calendar days, considerably under the usually recorded figure of eight plus days for all American industry. As might be

1. The Medical Bulletin of the Standard Oil Company (New Jersey) and Affiliated Companies, vol. 5, no. 1, June 1941.

expected, industrial injury rates have been regularly decreasing in this same group of employees. Sickness disability, however, has regularly increased for the past five years or more. One reason has been the increased incidence of common colds and influenza, a situation noted even in the group of employees working in the tropics. There are other more obscure causes, related to liberalization of sickness benefit plans, labor unrest and general apprehension resulting from world disturbances. Another curious and unexplained statistical result is the higher incidence of appendicitis in our own Southwest. An epitomized statistical summary is itemized in table 2. The column headed "Noneffective Rates" refers to the average daily number of disabled employees per thousand. This method of estimating economic loss resulting from sickness and injury is considered to be more useful than frequency rates alone.

A good share of investigation is directed at problems in sanitation and tropical medicine, especially malaria and amebiasis. Additional observations are being made on the effect of influenza vaccine on volunteers. A systematic study is in progress of 800 employees with hypertension on whom accurate medical records have been maintained for twenty years.

These facts and relationships about one of the large industrial organizations of the world were displayed in exhibit form at the recent annual session of the American Medical Association in Cleveland. Perhaps if other similar organizations would do likewise the general profession would obtain a far better realization of the modern objectives of industrial health.

MISSOURI GROUP HOSPITAL SERVICE

According to a report on five years of operation, the Group Hospital Service of Missouri is "the first community voluntary service plan to be inaugurated by a medical society in cooperation with the hospitals." It also claims to have established, during these five years, reserves which are among the three highest in the country and "to be the first to serve rural areas through a State Farm Bureau Federation."

The principal shortcoming at this time, according to the report, is the need of an even lower cost plan to reach the more limited and less privileged income group of workers. A committee of the trustees is at work and will present findings to the trustees in due course. In this way it is hoped to reach the great percentage of American workers earning less than \$1,200 annually.

Comparing the fiscal years 1939-1940 and 1940-1941, there has been an increase of 58 per cent in assets and 51 per cent in membership, while administrative costs have decreased from 15.1 per cent to 13.2 per cent. There has been a slight rise in the number of days of hospitalization per member year after the member has been in the plan for three years, and a general rise in the percentage of the income paid for maternity care. The report classifies all diseases hospitalized by average hospital days and amounts paid by Group Hospital Service.

WOMAN'S AUXILIARY

Georgia

The Woman's Auxiliary to the Georgia Medical Society held a recent meeting at the home of Mrs. J. H. Pinkolsier in Savannah, Mrs. J. C. Metts presiding. A report from the Christmas card chairman, Mrs. J. E. Porter, showed a profit of \$49.79 from the sales.

It was decided that the health committee and public relations committee place the pamphlet "Priceless Heritage" in beauty parlors and other suitable public places.

W. W. McCune, assistant school superintendent, gave an illustrated talk on "Our Health Program."

The Woman's Auxiliary to the Baldwin Medical Society held a recent meeting at the home of Mrs. C. B. Fulghum. Dr. J. R. Litton gave a talk on public health work. It was announced that members will contribute books and magazines to the Baldwin Blues' reading room.

Illinois

The Bureau county auxiliary held a joint meeting at Princeton with the auxiliary of the North Central Illinois Medical Association. The program, of which Mrs. M. A. Nix was chairman, opened with a tea at the Nix home. Dinner was served at the Presbyterian Church, after which Mrs. H. J. Dooley spoke on "The Aims of the Auxiliary," and Dr. Harold Camp, secretary to the Illinois State Medical Society, talked on "What the Auxiliary Can Do to Help Medicine."

Michigan

The project for the year of auxiliary to the Grand Traverse-Benzie-Leelanau Medical Society was a drive for funds for an iron lung to be donated to Munson Hospital. The drive was successful; they purchased an iron lung, costing \$1,500, and an infant respirator for the hospital, at a cost of \$375, and had some funds left.

The members of the auxiliary to the Ingham County Medical Society entertained their husbands with a Bohemian feast which preceded the yearly Keno Party of the society. This event has been enjoyed for several years and receives enthusiastic support.

Oregon

The Woman's Auxiliary to the Multnomah County Medical Society met recently with fifty-six members present. Dr. Edward Hume of the National Christian Mission spoke on

"Religion and Health." Later Mr. W. Jay Smith, president of the Oregon Wild Life Federation, addressed the group on "Conservation of Wild Life in Oregon." A movie entitled "The Polluted Willamette" was shown.

Pennsylvania

At a meeting of the Allegheny County auxiliary the membership chairman, Mrs. Joseph Soffel, presented the names of sixteen new members. The past president of the state society, Dr. Charles H. Henninger, talked on "Medical Preparedness." The remainder of the afternoon program was a musicale by Matilde McKinney, pianist of the Pittsburgh Symphony Orchestra.

Texas

Bowie-Miller counties auxiliary met recently at the home of Mrs. Roy F. Baskett, Texarkana, with Mrs. Tyson presiding.

Dr. Preston Hunt, president of the state medical association, spoke on "How the Auxiliary Serves the Medical Profession." Dr. W. W. Bauer of the Bureau of Health Education of the American Medical Association addressed several groups in Texarkana, February 11, under the auspices of the auxiliary: Texarkana Rotary Club, Texarkana College Assembly, Arkansas High School Assembly and a public meeting at the Congregational Church. Dr. Bauer's appearance in Texarkana under the auspices of the auxiliary was in celebration of Doctor's Day. Members of the committee in charge of this function were Mes. Ralph Cross, Roy Baskett, Harry Murry, William Hibbitts, H. E. Longino, S. A. Collom Jr., J. T. Robison, W. Decker Smith and Reavis Pickett. Mrs. Collom was general chairman of arrangements for Doctor's Day.

CORRECTION

Honorary Members.—At the recent annual meeting of the Woman's Auxiliary to the American Medical Association in Cleveland, the auxiliary voted to confer honorary membership on Mrs. Samuel Clark Red, Houston, Texas; Mrs. Franklin P. Gengenbach, Denver; Mrs. John O. McReynolds, Dallas, Texas, and Mrs. Willard C. Bartlett, St. Louis. The name of Mrs. V. E. Holcombe, Charleston, W. Va., was erroneously included in this list when published in *THE JOURNAL* July 12, page 125.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Human Case of Plague.—A fatal human case of plague has been reported in Siskiyou County, with onset on June 14 and death on June 26. The disease was reported in a 10 year old boy residing near Montague. The diagnosis was confirmed bacteriologically. According to *Public Health Reports*, July 4, the source of the infection has not been determined, but it is believed to have been ground squirrels.

COLORADO

Personal.—Dr. George W. Miel, for forty-seven years a member of the staff of St. Anthony's Hospital, Denver, was honored at a banquet and celebration in the nurses' home at the hospital recently in recognition of his long service.

State Furnishes Sulfathiazole for Gonorrhea.—The division of venereal disease control of the state department of health has made available to all physicians in the state free drugs for the treatment of medically needy patients infected with gonorrhea. Sulfathiazole will be distributed in individual bottles of fifty tablets on request by any physician who reports a case of gonorrhea on the regular confidential report card.

CONNECTICUT

Annual Clinical Congress.—The seventeenth clinical congress of the Connecticut State Medical Society will be held at the Sterling Law Buildings, New Haven, September 16-18. The following out of state speakers are on the program:

Dr. Frank H. Lahey, Boston, President of the American Medical Association, Estimation and Management of the Bad Surgical Risk Case.
Dr. Oscar F. Cox, Boston, Treatment and Nationwide Control of Gonococcal Infections.

Dr. Emil Novak, Baltimore, Female Hormones in Clinical Medicine.
Drs. James L. Poppen and Gilbert E. Haggart, Boston, The Best Method of Examining a Back.

Dr. Robert H. Kennedy, New York, Treatment of Fresh Wounds: Chemotherapy, Closed Plaster, etc.

Dr. Eli Jefferson Browder, Brooklyn, Immediate Treatment of Head Injuries.

Dr. Yale D. Koskoff, Pittsburgh, Demonstration of Essentials of a Neurological Examination for the General Practitioner.

George St. J. Perrott, Bethesda, Md., Physical Defects in the General Population.

Dr. Irvine H. Page, Indianapolis, Hypertension.

Dr. Ernst P. Boas, New York, Predisposing Factors in Myocardial Infarction.

Dr. Samuel A. Levine, Boston, Modern Treatment of Congestive Heart Failure.

Dr. Frank D. Lathrop, Boston, Recent Developments in the Treatment of Deafness.

Dr. Burrill B. Crohn, New York, Diagnosis and Treatment of Bleeding from the Stomach.

Dr. Thomas Francis Jr., New York, Treatment of Virus Infections.

Dr. Grantley W. Taylor, Boston, Mouth Tumors.

Dr. Matthew Walzer, Brooklyn, Gastrointestinal Allergy.

Dr. Jerome P. Webster, New York, Modern Treatment of Burns.

A feature will be the special course in traumatic surgery to be given under the direction of Dr. Samuel C. Harvey, William H. Carmalt professor of surgery, Yale University School of Medicine. It will begin during the congress and continue at weekly intervals until completed.

FLORIDA

Changes in Health Officers.—Dr. Jack B. Eason, director of the maternal and child health division of the Arizona State Board of Health, Phoenix, has been appointed director of the Lake County Health Department, succeeding Dr. Arthur W. Newitt, Tavares, who has been named director of the bureau of local health service of the state board of health, it is reported.

Special Society Elections.—Dr. Sherman B. Forbes, Tampa, has been elected president of the Florida Society of Ophthalmology and Otolaryngology, succeeding Dr. Hermon Marshall Taylor, Jacksonville. Other officers include Drs. Shaler A. Richardson, Jacksonville, vice president, and Carl E. Dunaway, Miami, secretary-treasurer. Dr. Wiley M. Sams,

Miami, was elected president of the Florida Association of Dermatology and Syphilology and Dr. Lauren M. Sompayrac, Jacksonville, reelected secretary. Officers chosen by the Florida Association of Industrial Surgeons were Drs. Frank D. Gray, Orlando, president-elect; George Frederick Oetjen, Jacksonville, president; William G. Harris, Jacksonville, vice president, and Kenneth A. Morris, Jacksonville, secretary. The Florida Radiological Society elected the following officers: Drs. John N. Moore, Ocala, president; Elliott M. Hendricks, Fort Lauderdale, vice president, and Walter A. Weed, Orlando, secretary.

GEORGIA

Personal.—Dr. Frank K. Boland, Atlanta, was elected president of the Emory University Alumni Association at the annual meeting in June, and Benjamin T. Carter, D.D.S., Atlanta, and Dr. Harold J. Starr, Chattanooga, Tenn., were elected vice presidents.

Prize Winning Papers.—The Fulton County Medical Society, Atlanta, announces that the following papers have been given cash awards in the 1941 competition. Both were submitted from Grady Hospital. First prize of \$20 went to Drs. Harry H. Clemons and H. Stephen Weems for their work on "Staphylococcal Pneumonia in Infants: Occurrence of Pneumopyothorax," and second prize of \$10 to Drs. Abraham S. Velkoff and Robert F. Mabon for "Reliability of the Fishberg Concentration Test in Normal Pregnancy and the Puerperium."

ILLINOIS

Typhoid Outbreak.—Eight cases of typhoid were reported to the state health department from DuQuoin between July 7 and August 1. The source of the outbreak had not been determined at the time of the report.

Epidemiologist for State Institutions.—Dr. Arnold M. Cohn, district health superintendent in charge of Christian, Fayette, Effingham, Montgomery and Shelby counties with headquarters at Pana, has been appointed to the newly created position of communicable disease consultant and epidemiologist from the department of public health to the eighteen institutions under the state department of public welfare.

Incubators Available for Loan.—Two hundred metal incubators for the care of premature babies are now available on loan throughout the state. They were built at the request and under the supervision of the state department of public health by the Springfield Work Experience Center of the National Youth Administration and will be placed in each of the state's twenty-one district health offices, ready for speedy emergency use in supplementing the permanent incubator facilities of hospitals. Among the 4,464 infant deaths reported in Illinois in 1939 nearly a third, 1,431, were attributed directly to premature birth.

Chicago

Course in Pediatrics.—The Children's Memorial Hospital will sponsor a graduate course in pediatrics, October 13-November 8. The work will be at the hospital with the exception of one afternoon a week at the Municipal Tuberculosis Sanitarium and one period a week in the contagious department of Cook County Hospital. The course is intended for general practitioners and for those especially interested in pediatrics. The fee will be \$100. Registration should be made at least one month before entrance if possible and should be accompanied by a \$10 deposit. The deposit will apply on the fee and will be refunded if the applicant is unable to take the course. Information may be obtained from the Children's Memorial Hospital, 707 Fullerton Avenue, telephone Diversey 4040.

INDIANA

Personal.—Dr. Robert B. Sanderson, since 1932 superintendent of Healthwin Hospital, near South Bend, has resigned. Dr. Edward W. Custer, assistant medical director of the state tuberculosis sanatorium at Hamburg, Pa., was named his successor, effective August 1.—Dr. Robert E. Jewett, Wabash, has been appointed assistant chief of the bureau of maternal and child health in the state board of health in Indianapolis. Dr. Jewett was formerly in charge of maternal and child health services in the state health department of Maine and recently took a degree in public health at the University of Michigan.—Dr. Wesley M. Hall, Rising Sun, has been appointed to succeed the late Dr. George H. Hansell, Rising Sun, as health commissioner of Ohio County.

IOWA

Interstate Malaria Conference.—The Interstate Malaria Survey, organized in 1939 by health officers and sanitary engineers of the upper Mississippi River basin states in collaboration with the U. S. Public Health Service, held a conference in Davenport on July 23. This group has studied various aspects of the malaria problem and is planning a campaign for the elimination of mosquito-breeding swamps and conditions that permit mosquitos to thrive, it was said. A feature of this year's discussions was consideration of sewage disposal plants. Dr. Walter L. Bierring, Des Moines, health officer of Iowa, is chairman of the group. The states represented are Minnesota, Wisconsin, Illinois, Iowa, Missouri and Indiana.

KANSAS

State Board Election.—Dr. Mirl C. Ruble, Parsons, was elected president of the Kansas State Board of Medical Registration and Examination at its annual meeting in Kansas City, June 17, and Dr. John F. Hassig, Kansas City, was reelected secretary. Other members of the board are Drs. Henry E. Haskins, Kingman; James E. Henshall, Osborne; Chester E. Joss, Topeka; Omar L. Cox, Iola, and Ralph G. Ball, Manhattan.

Society News.—Drs. Charles K. Shofstall and Charles C. Dennie, Kansas City, Mo., addressed the Golden Belt Medical Society, July 10, in Manhattan on "Routine Office Procedure for Treatment of the More Common Pharyngeal and Nasal Conditions" and "Dermatoses in Infants and Children" respectively.—Dr. Vern L. Pauley, Wichita, addressed the Cowley County Medical Society, June 19, in Arkansas City on "Treatment of the Prostate Gland" and Dr. Charles T. Moran, Arkansas City, on "Masking of Symptoms Caused by Sulfanilamide in Mastoid Disease."—Drs. Arthur W. Corbett and David R. Davis, Emporia, discussed appendicitis in adults and children, respectively, before the Lyon County Medical Society in Emporia, July 1.—Drs. Abraham E. Hiebert and Joseph V. Van Cleve, Wichita, addressed the Pratt County Medical Society, June 27, in Pratt on "Burns" and "Diagnosis and Treatment of the Commoner Skin Ailments" respectively.—Drs. Henry N. Tihen and Fred J. McEwen, Wichita, addressed the quarterly meeting of the Southeast Kansas Medical Society in Altamont, June 18, on "Therapy in Gastrointestinal Diseases" and "Cardiac Emergencies and Their Treatment" respectively.—Speakers at a meeting of the Sumner County Medical Society in Wellington, June 19, were Drs. Ray A. West, Wichita, on "Toxemias of Pregnancy" and "The Role of Anesthetics and Analgesics in Obstetrics" respectively.

KENTUCKY

Personal.—Dr. Lenore V. L. Patrick, Williamstown, has resigned as health officer of Grant County to take a position as pediatric consultant to the Wisconsin State Board of Health in Madison.—Dr. Adam Stacy Jr., Pineville, has resigned as health officer of Bell County to enter private practice.—Dr. Joseph Scott Goodpaster, Owingsville, has resigned as health officer of Bath County to enter private practice, and the health unit has been discontinued.

LOUISIANA

Society News.—The Orleans Parish Medical Society was addressed, July 14, by Drs. Gilbert C. Anderson and Noah Leon Hart on "Intracranial Foreign Bodies—Review of Literature, Case Report"; Carlo J. Tripoli and Richard E. Selser, "Newer Developments in the Treatment of Cerebrospinal Fever," and William H. Harris and Herbert J. Schattenberg, "Anlage Tumors of the Lung: Their Protean Histological Patterns in Bronchiogenic Neoplasia."

MICHIGAN

Society News.—Dr. William H. Alexander, Iron Mountain, was named president-elect of the Upper Peninsula Medical Society and Dr. Richard A. Burke, Palmer, became president at the annual meeting in Ironwood, July 17-18.—Dr. Henry Cook, Flint, discussed "Industrial Health and the General Practitioner" before the Muskegon County Medical Society in Muskegon, June 20.

Professor Appointed.—Dr. Ivan B. Taylor, Philadelphia, has been appointed professor of anesthesia at Wayne University College of Medicine, Detroit. Dr. Taylor graduated from

the University of Michigan Medical School, Ann Arbor, in 1932 and later was instructor in anesthesia at the University of Wisconsin Medical School, Madison. Recently he has been anesthetist at the Pennsylvania Hospital, Philadelphia.

Changes in Health Officers.—Dr. Sidney I. Franklin, director of health in Butler County, Ky., has been appointed in charge of the district health unit covering Mackinac and Luce counties with offices in Newberry.—Dr. Otto K. Engelke, Marshall, has been appointed director of the district health unit in Washtenaw County, with offices in Ann Arbor.—Dr. David J. Sobin has been appointed health officer in Carsonville, where he has been practicing medicine.

Dr. Muehlberger to Head State Crime Laboratory.—The Michigan Department of Health has established a crime detection laboratory in cooperation with the Michigan State Police with Clarence W. Muehlberger, Ph.D., Chicago, coronor's toxicologist for Cook County, Ill., as director. The new unit will be in two divisions, one in the health department's bureau of laboratories, where the work in toxicology will be carried on, and the other, a ballistics laboratory, in state police headquarters in East Lansing. In addition to the investigations for the detection of crime, the laboratory will make studies of the causes of occupational diseases in cooperation with the bureau of industrial hygiene. Dr. Muehlberger received the degree of doctor of philosophy at the University of Wisconsin, Madison, in 1923 and was on the faculty of the university from 1920 to 1930. He has been associate professor of pharmacology and toxicology at Northwestern University since 1930 and has also lectured on toxicology at the University of Illinois College of Medicine and the University of Chicago.

MINNESOTA

Personal.—Dr. Ernest M. Kingsbury, Clearwater, has recently been named chief medical officer at the state reformatory at St. Cloud; he will continue his Clearwater practice, maintaining evening office hours there.—Dr. Russell R. Hendrickson, Wabasha, has been named superintendent and medical director at Sand Beach Sanatorium, Lake Park, succeeding Dr. Leon H. Flancher, resigned.—Dr. James Lawrence McLeod, Grand Rapids, took office, July 1, as a district governor of Rotary International.

Faculty Changes at the University.—Dr. Clarence M. Jackson, professor and head of the department of anatomy at the University of Minnesota Medical School, Minneapolis, since 1913, retired at the end of the school year and was made professor emeritus. Dr. Jackson, who first became associated with the school in 1900 as assistant professor of anatomy, became professor in 1902 and head of the department in 1913. In addition he served as dean from 1909 to 1913 and was acting dean of the graduate school in 1917-1918 and in 1925. A committee consisting of Edward A. Boyden, Ph.D., chairman, Andrew T. Rasmussen, Ph.D., and Hal Downcy, Ph.D., has been appointed to administer the department for the coming year. Dr. Horace Newhart, professor of otolaryngology and director of the division of otology, rhinology and laryngology, has resigned to devote his time to private practice and Dr. Lawrence R. Boies, clinical associate professor of ophthalmology and otolaryngology, has been appointed director of the division. Dr. Newhart had been associated with the faculty since 1912. Other retirements were those of Drs. James Frank Corbett as clinical professor of surgery, Walter R. Ramsey as clinical associate professor of pediatrics, Harry P. Ritchie as clinical professor of surgery, Orianna McDaniel as clinical associate professor of preventive medicine and public health, and Anton G. Wethall as clinical assistant professor of urology. Dr. Charles A. Reed, associate professor of orthopedic surgery, also resigned to devote full time to private practice.

MISSOURI

Advisory Committee Named to Recommend Health Appointees.—A representative health and hospital advisory committee was recently appointed by Mayor Becker of St. Louis to obtain recommendations for appointments to major health, hospital and institutional positions, newspapers reported on June 22. Members of the committee include:

Dr. Joseph C. Peden, president, St. Louis Medical Society.
Alphonse M. Schwitalla, S.J., dean of the St. Louis University School of Medicine.
Dr. Frank R. Bradley, superintendent of Barnes Hospital.
Philip A. Shaffer, Ph.D., dean, Washington University School of Medicine.
H. J. Mohler, president, St. Louis Hospital Council.
Dr. Arthur N. Vaughn, president of the National Medical Association.

Society News.—Dr. Stanley F. Hampton, St. Louis, addressed the St. Francois-Iron-Madison-Washington-Reynolds Counties Medical Society in Farmington, June 27, on "Allergy in Relation to General Practice."—The Buchanan County Medical Society was addressed in St. Joseph, June 4, by Drs. James O'Donoghue on "Osteochondritis (Nonsuppurative Epiphysitis)" and Gaylord T. Bloomer, "Treatment for Epiphysitis." Both are of St. Joseph.

NEW YORK

Lake Keuka Meeting.—The summer meeting of the Lake Keuka Medical and Surgical Association was held, July 10-11, at the Keuka Hotel on Lake Keuka. The speakers included:

Dr. Louis Faugeres Bishop Jr., New York, Senile Heart; Observations, Prognosis and Management.
Dr. Lee Adrian, " " Management of Fractures.
Dr. John W. N. " " from a General Practitioner's Point of View.
Dr. James E. King, Buffalo, Pruritus Vulvae.
Dr. Donald Guthrie, Sayre, Pa., Preoperative Care of Toxic Goiter Patient.

Dr. Leon M. Kysor, Hornell, is president of the association, Dr. Noble R. Chambers, Syracuse, vice president and Dr. Virgil H. F. Boeck, Dundee, secretary.

New York City

Hospital News.—The psychiatric service of Lebanon Hospital has been reorganized with Dr. William V. Silverberg in the newly created position of associate in psychiatry and also as chief of the mental hygiene clinic.—Mr. Homer Wickenden, formerly general director of the United Hospital Fund, has been appointed assistant director of the New York Medical College, Flower and Fifth Avenue Hospitals.

Friday Afternoon Lectures.—The Medical Society of the County of Kings has announced its fall series of Friday afternoon lectures. The program for October is as follows:

October 3, Dr. Burrill B. Crohn, The Present Concept of Colitis and Its Management.
October 10, Dr. Alfred H. Iason, Hernia.
October 17, Dr. George A. Sheehan, The Approach to Differential Diagnosis of Medical Conditions.
October 24, Dr. Simon R. Blatteis, Recent Concepts of Rickettsial Diseases: Endemic Typhus, Its Diagnosis and Treatment.
October 31, Dr. Arthur C. DeGraff, Recent Advances in Digitalis Therapy with Particular Attention to the Use of Pure Glycosides.

Postgraduate Courses in Clinical Medicine.—During the coming year Mount Sinai Hospital will present postgraduate courses in clinical medicine in cooperation with Columbia University College of Physicians and Surgeons. One series of part time courses on various topics will be offered from October 27 to December 20. Preceding these October 6 to 10 there will be an intensive full time course on syphilis. A second series will be presented from February 2 to March 28, 1942. In addition three full time courses of four weeks each will be offered in the spring: cardiovascular diseases, April 6 to May 2; gastroenterology, April 6 to May 2, and internal medicine, May 4 to 29. Requests for information should be addressed to the Secretary for Medical Instruction, Mount Sinai Hospital, Fifth Avenue and 100th Street, New York.

Appointments at New York University.—Dr. Colin M. MacLeod, an associate of the Rockefeller Institute for Medical Research, has been appointed professor of bacteriology and director of the bacteriologic laboratories at the New York University College of Medicine. He succeeds Dr. Thomas Francis Jr., who resigned to become professor and head of the department of epidemiology at the new University of Michigan School of Public Health in Ann Arbor. Alwin M. Pappenheimer Jr., Ph.D., assistant professor of biochemistry in bacteriology, University of Pennsylvania School of Medicine, Philadelphia, has been appointed assistant professor of bacteriology. Dr. Frank C. Combes, New Rochelle, associate professor of dermatology and syphilology, has been made full professor, and Dr. James A. Shannon, formerly assistant professor of physiology, has been made assistant professor of medicine and director of the research services on the university's division at the Welfare Hospital for Chronic Diseases.

OHIO

Society News.—Dr. James C. Walker, Dayton, addressed the Greene County Medical Society, Xenia, June 12, on "Treatment of Fractures of the Neck of the Femur."—Dr. Ray W. Kissanc, Columbus, spoke on "Cardiac Contusion" at a meeting of the Marion Academy of Medicine, Marion, in June.—Dr. Edward O. Harper, Cleveland, addressed the Portage County Medical Society, Ravenna, June 19, on "The Hysterias."—Speakers who addressed the Adams County Medical Society, Manchester, June 18, were Drs. Edward S.

Jones, Erie, Pa., on "The Tuberculosis Patient, the Diagnosis, Treatment and Prognosis"; Joseph E. Pirrung and Elmer A. Schlueter, Cincinnati, on "Ulcers and Cancer of the Stomach."

PENNSYLVANIA

Society News.—The Pittsburgh Pediatric Society held a meeting in connection with a "pediatric clinic day" at the Windber Hospital, Windber, June 25. The speakers were Drs. Hyman A. Slesinger, Windber, on "Allergy in Childhood"; Elwood W. Stitzel, Altoona, "Schüller-Christian Disease"; Harold Antiles, Brooklyn, "Undulant Fever" and Paul J. McGuire, Homestead, "Diagnosis of Whooping Cough."

Philadelphia

Personal.—Dr. Alexander J. Steigman, formerly of the staff of the Children's Hospital and the department of pediatrics of the University of Pennsylvania School of Medicine, has left for England to join the American Red Cross-Harvard University Hospital for Infectious Diseases.—Dr. Claude P. Brown, formerly director of the biologic laboratories of the National Drug Company, has been appointed assistant director of the Pennsylvania State Board of Health Laboratories in Philadelphia.

Centennial Celebration of Mental Disease Department.—The department for mental and nervous diseases of the Pennsylvania Hospital held a centennial celebration in June in commemoration of the opening in 1841 of a new building for the mental patients of the hospital. A public meeting and reception were held in the department with addresses by David E. Williams Jr., president of the board of managers; Drs. Lauren H. Smith, physician in chief and administrator; Earl D. Bond, director of research, and Edward A. Strecker, consultant in chief. A medical meeting with papers by the psychiatric staff was also a feature. Pennsylvania Hospital, founded in 1751, is said to have been one of the first hospitals to care for mentally ill patients with the same consideration as shown to the physically ill. Dr. Benjamin Rush, who has been called the "father of American psychiatry," was one of its early physicians in chief.

TENNESSEE

New Health Officers.—Dr. W. D. Burkhalter, associate director of county health work in the state department of health of Alabama, Montgomery, has been appointed health officer of Shelby County with headquarters in Memphis. He succeeds Dr. Robert D. Hollowell, who has gone to St. Petersburg, Fla., as health officer of Pinellas County. Dr. Goldsborough Foard McGinnes, consultant in venereal disease control in the Shelby County health department, has been appointed director of venereal disease control in the state department of health at Nashville.—Dr. Thomas L. Harvey, Newport, health officer of Cocke County, has been transferred to the Dyer-Crockett counties health district with headquarters in Dyersburg. Dr. Luke W. Frame, Ripley, has succeeded Dr. Harvey.—Dr. Arthur K. Husband, Waterbury, Conn., has been appointed health officer of Unicoi County to succeed Dr. Landon H. Gurnee, Erwin, resigned.—Dr. Carl F. Luckey, Jackson, has been appointed health officer of Johnson County in Mountain City.

TEXAS

Allergy Society Reorganized.—The Texas Allergy Association at its annual meeting in Fort Worth in May changed its name to the Southwest Allergy Forum and elected Drs. Homer E. Prince, Houston, president and Simeon H. Hulsey, Fort Worth, secretary. The next meeting will be held in Little Rock, Ark., probably in March 1942.

UTAH

State Medical Election.—Dr. Edwin M. Neher, Salt Lake City, was named president-elect of the Utah State Medical Association at the annual meeting in Salt Lake City, June 11-12, and Dr. John R. Anderson, Springville, became president. Vice presidents elected were Drs. John C. Hubbard, Price; David P. Whitmore, Roosevelt, and Ernest L. Hanson, Logan. The next annual session will be in Provo.

VIRGINIA

Neuropsychiatric Meeting.—Dr. Leo Kanner, Baltimore, was the guest speaker at a meeting of the Neuropsychiatric Society of Virginia in Richmond, June 18, on "Psychotherapy in Children." Other speakers were Drs. Howard R. Masters, Richmond, on "Psychodynamic Aspects of War and Extenu-

ating Crises"; James B. Funkhouser, Marion, "A Description of the Rorschach Experiment," and Oscar B. Darden, Richmond, "Psychoses Among Students Requiring Hospitalization."

Symposium on Industrial Health.—The committee on industrial health of the Medical Society of Virginia and the bureau of industrial hygiene of the state department of health will present the second symposium on industrial health at the Medical College of Virginia, Richmond, September 11-12, with the cooperation of the Virginia Manufacturers' Association and the Richmond Chamber of Commerce. Among addresses scheduled are:

- Dr. William J. McConnell, New York, Respiratory Diseases and Air Conditioning.
- Dr. Louis Schwartz, Bethesda, Md., Diagnosis, Treatment and Prevention of Industrial Dermatoses.
- Donald E. Cummings, B.S., Denver, subject to be announced.
- Dr. Theodore Lyle Hazlett, Pittsburgh, Placement of the Worker.
- Dr. Murray B. Ferderber, Pittsburgh, Selection of Heat in the Treatment of Plant Injuries.

There will be a symposium on industrial ophthalmology presented by Drs. Harry B. Stone, Roanoke; George H. Cross, Chester, Pa.; Rudolph C. Thomason, Richmond, and Charles N. Scott, Nitro, W. Va. Speakers in a symposium on injuries to the hand will be Drs. Sumner L. S. Koch, Chicago; Henry C. Marble, Boston, and Thomas Beath, Richmond. At an evening meeting, September 11, the speakers will be Philip Drinker, C.E., Boston, on "The Significance of Industrial Health in National Defense" and Dr. Edward J. Stieglitz, Garrett Park, Md., "Aging as a Problem of Industrial Health."

WYOMING

State Medical Election.—Dr. George H. Phelps, Cheyenne, was named president-elect of the Wyoming State Medical Society at the annual meeting in Casper. Dr. Lial S. Anderson, Worland, was made vice president and Dr. Marshall C. Keith, Cheyenne, was reelected secretary. The 1942 session will be held in Cheyenne.

GENERAL

Biologic Photographers to Meet.—The eleventh annual meeting of the Biological Photographic Association will be held at the Hotel Buffalo, September 11-13, in Buffalo. The program will emphasize methods and processes that are likely to contribute to national defense, according to an announcement. Visitors are welcome. Further information may be obtained from the Secretary, Biological Photographic Association, University Office, Magee Hospital, Pittsburgh.

Encephalitis Outbreak in Northwest States.—Sixty deaths have occurred in the outbreak of encephalitis that started about July 1 in North Dakota, the Associated Press reported August 7 (*THE JOURNAL*, August 9, p. 465). The disease has spread to South Dakota, from which 3 cases were reported, and Minnesota, in which there were 19, it was said. Dr. James P. Leake of the U. S. Public Health Service, Washington, D. C., and W. L. Jellison, an entomologist on the staff of the Rocky Mountain Laboratory of the public health service at Hamilton, Mont., have gone to Fargo to conduct an investigation.

Birth Rate Shows Upward Trend.—Provisional tabulations of births in 1940 indicate that the trend is upward, as it has been since 1933, the U. S. Bureau of the Census reports. There were 2,353,988 births reported, an increase of 91,260 over the final figure for 1939. The five states with the highest rates were New Mexico with 27.7 per thousand enumerated population, Utah 24.6, Mississippi 24.1, Arizona 23.5 and South Carolina 22.7. The rate for the District of Columbia was 23.1. The five states with the lowest birth rates were New Jersey with 14.1, New York 14.6, Connecticut 14.7, Rhode Island 15.1 and Missouri 15.5.

Society News.—Dr. Ernest M. Seydell, Wichita, Kan., was elected president of the American Otological Society at the annual meeting in May; Dr. Wesley C. Bowers, New York, vice president, and Dr. Isidore Friesner, New York, secretary. —The American Association for the Advancement of Oral Diagnosis will be held in New York, November 13-14, at the New York Academy of Medicine. Members of the medical and dental professions in the United States and countries of the Western Hemisphere who are interested are invited to attend. Programs may be obtained from the secretary, H. Justin Ross, D.D.S., 515 Madison Avenue, New York.

Outbreak of Poliomyelitis Spreads.—Twenty-two new cases of poliomyelitis in the Camp Forrest area of Tennessee were reported, August 10, according to the *Chicago Tribune*. Schools in Moore County, which were to have opened on August 11, were ordered to remain closed until September 1. —There were 125 cases in Alabama on July 25; 44 of the

total were in Birmingham and Jefferson County, the *Birmingham News* reported.—Georgia had 221 cases on July 25, with 65 in Atlanta, according to the *Atlanta Journal*.—Illinois had a total of 72 cases, with 33 in Cook County (including Chicago), the state health officer reported on August 7.—The *New York Times* reported on August 5 that 44 cases had occurred in New Brunswick, Canada, since July 14, with four deaths.

Bequests and Donations.—The following bequests and donations have recently been reported:

- Bryn Mawr Hospital, Bryn Mawr, Pa., \$10,000 from the estate of the late Emily Chapman Philler of Haverford.
- Stuyvesant Square, now the New York Skin and Cancer Hospital, and St. Luke's Hospital and the Hospital for the Ruptured and Crippled, New York, \$153,000 each from the estate of the late Mrs. Esther Hull Tremain of Dobbs Ferry; she also provided remainder interests in two \$50,000 trust funds for the Presbyterian and Roosevelt hospitals.
- Manhattan Eye, Ear and Throat Hospital, \$10,000, and Hospital for the Ruptured and Crippled, \$5,000 by the will of the late George Bliss Agnew. Both are in New York.
- Genesee Hospital, Rochester, N. Y., \$2,000 and three fifths of the residuary estate of the late Mrs. Katharine C. Butts.
- Grace Hospital and Children's Hospital, Detroit, \$5,000 each from the will of the late Dr. George R. Andrews.

Meeting on Neoplastic Diseases.—The annual meeting of the American Association for the Study of Neoplastic Diseases will be held at Garfield Hospital, Washington, D. C., September 4-6. Chairmen for the sessions and topics to be discussed are:

- Dr. Ramsay Spillman, New York, Lesions of Bone.
- Dr. Harry F. Friedman, Boston, Lesions of the Female Genital System.
- Dr. Leopold Clarence Cohn, Baltimore, Lesions of the Breast.
- Dr. Louis Wallace Frank, Louisville, Lesions of the Gastrointestinal Tract.
- Dr. Charles F. Geschickter, Baltimore, Lesions of the Lungs and Respiratory Passages.
- Dr. George Curtis Crump, Asheville, N. C., Lesions of the Lymphoid, Myeloid and Reticuloendothelial Systems.

Friday evening there will be a banquet at the Hotel Mayflower with Dr. John Shelton Horsley, Richmond, Va., as the guest of honor.

China Defense Supplies Commission Appoints Medical Adviser.—Dr. Frank Wang Co-Tui, associate professor of experimental surgery at New York University College of Medicine, New York, has been appointed medical adviser to the China Defense Supplies Commission established by President Roosevelt last April to supervise purchases under the lend-lease program. Dr. Co-Tui will also advise on medical purchases for China made by the American Red Cross and United China Relief. He is vice president of the American Bureau for Medical Aid to China, one of eight agencies now coordinated in United China Relief, which has undertaken to supply all personnel needs, to recruit Chinese physicians living abroad for service in the Chinese Medical Corps, to equip and support the emergency training centers in China for medical aides and to aid the Chinese National Health Administration in its antiepidemic control plan. The medical bureau has opened headquarters at 1790 Broadway, New York, where American physicians and nurses can apply for service in China. One ambulance corps of fifty American, British and Canadian volunteers left on June 23 for service along the Burma Road, with Dr. Robert B. McClure, formerly of Hwaikang, Honan, China, in charge.

Government Services

Identification Tag Shows Blood Type

A new identification tag recently adopted by the U. S. Navy includes in the information it bears each man's blood group and the date on which he received tetanus toxoid.

New Unit for Neuropsychiatric Research

A neuropsychiatric research unit has been established at the Veterans Administration Facility at Northport, L. I., to conduct clinical and laboratory research in connection with neuropsychiatric disabilities among veterans. Dr. James H. Huddleson, recently on the staff of the facility at Portland, Ore., will be the director of the unit and Dr. William J. Turner, recently at North Little Rock, Ark., will supervise the laboratory activities. Technical assistance will include a biochemist, an assistant statistician and laboratory technicians. An effort will be made to standardize diagnostic and therapeutic methods used in the management of neuropsychiatric diseases and the staff will give instruction in modern concepts to medical officers of the Veterans Administration detailed for this purpose, it was said.

Foreign Letters

LONDON

(From Our Regular Correspondent)

June 25, 1941.

The Supply of Physicians in Wartime

At a meeting of the General Medical Council the president expressed satisfaction that the government had been alive to the need for maintaining an adequate supply of physicians for civilian as well as for the combatant services. By a new order the government has permitted the council to register temporarily in the colonial or foreign lists physicians from the dominions, colonies, protectorates and allied and enemy European countries provided that they held suitable diplomas and served as medical officers in hospitals or institutions or in some service not involving attendance on patients in their homes. To date two hundred and ninety-four such names had been registered. The credentials of American physicians volunteering in response to Mr. Roosevelt's appeal would be submitted to American bodies for approval. An offer from the Rockefeller Foundation to provide a two years course of free clinical instruction for twenty-five British medical students had been gratefully accepted. The selected candidates would serve as student ambassadors and should bring back interesting reports on medical education in the United States and Canada. Their two years over there would count as part of their curriculum here.

The Treatment of Fractures in the Emergency Hospitals

The emergency hospitals have been organized by the government for the treatment of the accidents sustained by civilians in enemy attacks. The minister of health has reviewed the facilities available for the treatment of fractures with a view to insuring that all patients receive the treatment best suited to their needs and are placed as early as possible under surgeons experienced in their management and in a hospital well equipped to deal with them. As these do not exist in all hospitals, he has decided to designate, in addition to the existing orthopedic centers, three new classes of fracture treatment centers. The first will be designated hospitals which are suitable, from their situation, for cases requiring hospital treatment for a considerable time. They will be under the direction of a surgeon experienced in the treatment of fractures and will provide massage, electrotherapy, remedial exercises and occupational therapy. The second class designated will have similar facilities but, from their position, not be suitable for long stay cases. They will be designated fracture departments for ambulant and short stay cases. The third class will provide special clinics suitably situated for outpatient treatment within reach of the patients' homes after discharge from the hospitals of the previous classes which are not so situated.

Work at the London School of Tropical Medicine

The war has seriously affected the work of the London School of Tropical Medicine, but programs of research have been carried out as well as a limited amount of teaching, and short intensive courses have been given for those about to undertake service in the tropics. The department of clinical tropical medicine suffered a serious loss when the Hospital for Tropical Diseases was closed on the outbreak of war, but as a temporary measure ten beds have been allocated at the Dreadnought Hospital, Greenwich, for cases of the type which used to be admitted to the Hospital for Tropical Diseases. But the Dreadnought Hospital has since been damaged by enemy action, so that other provisions for the teaching of clinical medicine have had to be made. The department of parasitology has been transferred to a town a short distance

from London, where an investigation on subclinical helminthiasis in Great Britain is being continued, as well as other studies. Investigations on lice have occupied the department of entomology, and the use of modern insecticides has been carefully examined. In the public health department the behavior of the skin, especially in relation to the effects of clothing, has been studied.

Fresh Liver for Pernicious Anemia

Owing to the present shortage of supplies of raw liver, the Food Rationing Advisory Committee of the Medical Research Council was asked by the Ministry of Food to advise as to the need for special rations of fresh liver for the treatment of pernicious anemia. The committee advised that fresh liver is not necessary except in those rare cases in which parenteral injection of liver extract produces anaphylactic shock. The Ministry of Food has accordingly made no provisions for allowing extra rations of fresh liver in pernicious anemia in general but has arranged that on the production of a medical certificate that liver extract parenterally produces anaphylactic shock such rations may be obtained for particular patients. The advice of the committee is based on the following considerations: The treatment of pernicious anemia by parenteral liver extract is more efficient than that by ingestion of raw or lightly cooked liver; it is the cheapest method; under present conditions a continued supply of fresh liver cannot be guaranteed.

The treatment of pernicious anemia, says the committee, cannot be considered satisfactory unless the red corpuscles are maintained at 5 millions per cubic millimeter and the hemoglobin at 100 per cent. At lower figures the patient may feel well but there is danger of subacute degeneration of the cord developing. While the necessary values may be maintained by ingestion of fresh liver, the amounts required are such that few patients will take them indefinitely. On the other hand, intramuscular injections of 1 or 2 cc. of liver extract at intervals of seldom less than one or two weeks are sufficient.

The committee does not advise either the liquid or the powder preparations of liver designed for oral administration. Its reason is that, though efficacious, these preparations are uneconomical of the supply of raw liver available. About fifty times as much liver is required to produce a single dose as for parenteral administration. This objection does not apply to oral preparations made from the stomach.

Mr. Winston Churchill, F.R.S.

The fellowship of the Royal Society (F.R.S.) is the highest scientific distinction in this country and as a rule is conferred only on those who have done original scientific work of importance. The unusual ceremony has taken place of conferring the distinction on a man who is not a scientist but the value of whose work for the country cannot be exaggerated. At the cabinet room of the government, the president of the Royal Society, Sir Henry Dale, who has qualified as a physician and is an eminent biochemist, conferred the F.R.S. on the prime minister, Mr. Winston Churchill. Among the secretaries of the society present was the physiologist Prof. A. V. Hill, who is biologic secretary. After signing his name in the ancient charter book Mr. Churchill was shown the signature of his ancestor Sir Winston Churchill, father of the great duke of Marlborough, who was admitted an early fellow of the society in 1664.

Biochemist to Study the Food of the Air Force

The government has appointed a biochemist, Dr. T. F. Maeræ, and a specialist medical officer, squadron leader W. P. Stamm, to watch over the food supplies of the air force to insure that the greatest nutritional value is obtained. The biochemist will analyze the foods and experiment to discover the existence and extent of any deficiency in vitamins, min-

erals, salts, proteins, carbohydrates or fats. The specialist medical officer will watch for the earliest signs of food deficiency in the health of the men. Both will study the preparation and cooking of food at the various units, the planning of a balance ration from the available supplies and the prevention of waste.

Dr. Macrae has done much organic chemical research since graduating in 1927. After working in Glasgow for two years he undertook biochemical research at Munich University under Professor Wieland and later at the Lister Institute and the London Hospital. He has performed experiments and published reports of researches on food, yeast, bread, potatoes and the fattening of pigs.

Celebration of an One Hundred and Eleventh Birthday

Mr. Patrick Lucas Hamilton, an Irishman who lives at Pleasant Point, 12 miles from Timaru, New Zealand, has celebrated his one hundred and eleventh birthday, states Reuter. In honor of the occasion he sat for three hours in an easy chair, which his family had presented to him on his hundredth birthday. He was born in County Donegal and came to New Zealand in 1870.

BUENOS AIRES

(From Our Regular Correspondent)

May 29, 1941.

Adolescent Health in Buenos Aires

Prof. Florencio Bazán and Dr. G. Bayley Bustamante, pediatricians officially connected with the division of school hygiene of the national health department in Buenos Aires, recently prepared a report of investigations made by their division into the health condition of school youths at the age level of 12 to 18 years. Of the 27,000 examined during the first quarter of 1940, 3,500 were about 18 years old, 22,000 were 12 years old or somewhat older and only 1,200 were under 12 years of age. Accordingly, the statistics submitted in this report cover youths between incipient puberty and the termination of the growth period.

In general, 10.47 per cent of the 27,000 children presented an anomaly of some kind. This does not include dental caries, which was found in 34 per cent of the children. Twenty-eight per cent of the younger children in this survey showed some infection exclusive of infections of the eyes (15 to 21 per cent) and ears (5 to 8 per cent). Since the latter infections were included in the studies for the older children, it demonstrated that the pathologic index of the older children was six times lower than that of the younger.

In the health analysis of the older children a good general condition was found in 26,000 (96.07 per cent). In 1,000 (3.89 per cent) a lower health index was seen consisting in serious chronic nutritional disturbances but without definite sequels, congenital defects or other defects associated with partial deficiencies. In 10 (0.04 per cent) poor general health was observed, such as chronic disorders with general deficiencies, cardiopathies or tuberculosis. An unsatisfactory nutritional status was seen in a small number of cases (0.45 per cent). (Statistics covering 500,000 elementary school children showed nutritional impairment in 2.93 per cent.) Overnutrition in the sense of uncomplicated obesity was observed in 1.29 per cent and may be due to the metabolic changes in early puberty. Endocrine dysfunction was seen in 195 cases of adipositas hypogenitalis, in 5 cases of gynecomastia, in 3 of infantilism (Lorain type), in 3 of hyperthyroidism, in 1 case of exophthalmic goiter and in 1 case of hypoplasia genitalis. Atypical cases are not included in these figures. The disease index noted in these disorders (0.77 per cent) was much higher than that of elementary school children (0.05 per cent), owing to the greater age and development of the former. The circulatory disturbances observed were valvular involvements and amounted to only 0.2 per cent. These figures are based on clinical evaluation.

Electrocardiographic and roentgenologic methods would probably indicate a greater involvement. Only 30 cases of respiratory diseases were noted. However, common acute processes were not counted and no roentgenologic examinations were made. Nervous diseases were found in only 0.11 per cent, cutaneous diseases in 0.38 per cent (in elementary school children the rate was 1.76 per cent). Among otorhinolaryngologic diseases, hypertrophy of the tonsils and adenoids were as low as 0.52 per cent compared with a 9.57 per cent in children of elementary school age. The reduction is attributed to spontaneous regression or to medical care. Ocular disturbances were found in 5.36 per cent compared with a three times greater incidence in elementary children, the result, no doubt, of corrective measures taken. External deformities such as congenital malformation, hernia, scoliosis and flat foot amounted to 0.48 per cent; urogenital disturbances to 0.58 per cent, including 82 cases of testicular ectopy and 71 cases of varicocele.

The functions of the division of school hygiene consist not only in diagnosis and statistical surveys but in taking measures for early treatment. That public health studies are valuable can be gathered from the statistics furnished by the ministry of war regarding the fitness of examined recruits. In 1928 military unfitness amounted to 25.3 per cent. It rose to 42.1 per cent in 1939. The causes of unfitness assigned in 1939 in a report on 12,893 recruits of the first division (Buenos Aires, the capital) were insufficient body size 126, insufficient weight 366, insufficient chest index 3, constitutional weaknesses 1,527, nutritional and metabolic disorders 68, endocrine dysfunction 10, respiratory disorders 60, digestive disorders 1,613, circulatory disorders 150, urogenital disturbances 116, cutaneous disturbances 356, auditory disturbances 58, ophthalmologic disturbances 315, nervous disturbances 54, disturbances of hemopoietic organs 5, allergies and poisoning 10, infectious diseases 4, tuberculosis 44, congenital malformation, dystrophias, deformation and mutilation 997, traumas 94 and tumors 6. These conditions were found in 6,175 (47.1 per cent) of the 12,893 recruits.

Marriages

CHARLES GARDNER CHILD 3d, New York, to Miss Margaret McCrae Austin of Upper Montclair, N. J., June 14.

THOMAS GARDINER THURSTON, 2d, Taylorsville, N. C., to Miss Susan Rankin Fountain of Rocky Mount, June 10.

JAMES ANDRE LAMPHIER, Newton, Mass., to Miss Anne Fischer Nosworthy of Bronxville, N. Y., June 21.

WILLIAM HENRY BREEDEN, Bennettsville, S. C., to Miss Mary Fowler Robinson of Sand Spring, Md., in June.

WILLIAM TALIAFERRO THOMPSON JR. to Miss Jessie Gresham Baker, both of Richmond, Va., June 21.

EARL J. HOUGHTON to Miss Genevieve Fleishman, both of Davenport, Iowa, in Iowa City, June 25.

LONDON H. GURNEE, Erwin, Tenn., to Miss Doris Eakin of Lexington, Miss., in Memphis, June 8.

EDWARD HUGER ROBERTS, Choctolocco, Ala., to Miss Katherine Hall of Chicago, July 16.

LOUIS IACUEO, New York, to Miss Anne Victoria Spica of Mount Vernon, N. Y., June 10.

CHARLES HUGH MAGUIRE to Miss Sherley Chapman Jenkins, both of Louisville, Ky., July 2.

DAVID FERTIG, Hartsdale, N. Y., to Miss Catherine Campbell of White Plains, March 19.

JOHN HENRY BORN to Miss Eleanor Frederica Lehrfeld, both of New York, June 14.

WILLIAM F. KUBICEK, Cleveland, to Miss Lorell Watne of Nokomis, Ill., in June.

VIOLET GRAY HALFPENNY, Fairfield, Ala., to Mr. Lew Chauncey Wallace, June 14.

ROBERT J. HALEY JR. to Miss Ethel Brewer, both of Paragould, Ark., in June.

CHARLES PAINE JR. to Miss Mary Halbrook, both of Atlanta, Ga., in June.

Deaths

Walter Carl Klotz ☉ New York; Columbia University College of Physicians and Surgeons, New York, 1898; assistant professor of public health and preventive medicine at the Cornell University Medical College; at one time associate professor of phthisiology at the University of Virginia Department of Medicine, Charlottesville, and instructor in medicine at the University of California Medical Department, Los Angeles; member of the American Clinical and Climatological Association; at various times medical director of the Vermont Sanatorium, Pittsford, Blue Ridge Sanatorium, Charlottesville, Va., and the Johnson City (Tenn.) National Sanatorium; formerly physician in charge of the Barlow Sanatorium, Los Angeles; served as associate medical director of the commission for tuberculosis in France, 1918-1919; for many years director of the outpatient department of New York Hospital; aged 65; died, June 29.

Elmore B. Tauber ☉ Cincinnati; Medical College of Ohio, Cincinnati, 1902; chairman of the Section on Dermatology and Syphilology of the American Medical Association, 1930-1931; professor of dermatology and syphilology at the University of Cincinnati College of Medicine; member of the American Dermatological Association, American Academy of Dermatology and Syphilology, Pan American Dermatological Society, tenth International Dermatological Congress, Society for Investigative Dermatology, Mississippi Valley Dermatological Society and the Central States Dermatological Society; on the staffs of the Cincinnati General Hospital, Jewish Hospital, Children's Hospital and the Holmes Hospital; aged 62; died, June 23, of a streptococcal infection.

James Ely Talley, Lima, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1892; emeritus professor of cardiology at the University of Pennsylvania Graduate School of Medicine; fellow of the American College of Physicians; served in the navy during the World War; one of the founders and past president of the Philadelphia Heart Association; one of the founders, for many years on the staff and a member of the board of directors of the Babies' Hospital, Philadelphia; member of the board of governors of the Children's Heart Hospital, Philadelphia; consulting physician on the staff of the Presbyterian Hospital and the Woman's Hospital, Philadelphia; aged 76; died, July 3, of arterial cerebral thrombosis.

John P. Fletcher, ☉ Lieutenant Colonel, U. S. Army, retired, Carlisle, Pa.; University of Virginia Department of Medicine, Charlottesville, 1908; entered the medical corps of the United States Army as a first lieutenant in 1910, in 1913 was appointed a captain, a major in 1917 and retired with rank of lieutenant colonel June 22, 1930 for disability in line of duty; was in active duty from June 23, 1930 to Oct. 31, 1930; fellow of the American College of Surgeons; served during the World War; aged 56; died, May 10, of uremia.

Charles Lloyd Connor ☉ San Francisco; Baylor University College of Medicine, Dallas, Texas, 1920; professor of pathology at the University of California Medical School; instructor of pathology at the Harvard Medical School, Boston, in 1925; member of the American Association of Pathologists and Bacteriologists and the American Society for Experimental Pathology; on the staff of the University of California Hospital; aged 49; died, June 12, of coronary arteriosclerosis.

George Flanders Wilson, Portland, Ore.; University of Virginia Department of Medicine, Charlottesville, 1879; University of the City of New York Medical Department, New York, 1880; emeritus professor of surgery at the University of Oregon Medical School; for many years on the staff of the Good Samaritan Hospital; aged 82; died, June 27, of hemiplegia resulting from hypertension.

James Alexander Craig ☉ Gary, Ind.; University of Maryland School of Medicine, Baltimore, 1908; fellow of the American College of Surgeons; served during the World War; attending surgeon, Methodist and St. Mary's Mercy hospitals, and Lake County Tuberculosis Sanitarium, Crown Point; formerly member of the school board; aged 61; died, July 2, of mitral regurgitation.

William Ernest Ramsay, Perth Amboy, N. J.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1888; member of the Medical Society of New Jersey; formerly health officer; at one time state senator; for many years on the staff of the Perth Amboy Hospital; aged 74; died, June 26, of chronic myocarditis and coronary embolism.

William Tell Oppenheimer ☉ Richmond, Va.; Medical College of Virginia, Richmond, 1881; University of the City of New York Medical Department, 1882; fellow of the American College of Surgeons; past president of the Richmond Academy of Medicine; past president of the city board of health; aged 80; died, June 11, of cardiorenal disease.

Alfred William MacPherson ☉ Los Angeles; College of Medical Evangelists, Los Angeles, 1929; member of the Nevada State Medical Association; assistant professor of anesthesiology at his alma mater; on the staff of the White Memorial Hospital; aged 39; died, June 18, following an operation on adhesions, causing chronic obstruction.

Eugene Augustus Vickery ☉ Medical Inspector, Commander, United States Navy, retired, Boston; Harvard Medical School, Boston, 1903; fellow of the American College of Surgeons; entered the navy in 1904 and retired in 1930 for incapacity resulting from an incident of service; aged 62; died, June 22, of coronary thrombosis.

Charles Leo McCrossan, Somerville, Mass.; Harvard Medical School, Boston, 1910; member of the Massachusetts Medical Society and the New England Obstetrical and Gynecological Society; member of the board of health; on the staff of the Somerville Hospital; aged 54; died, June 26, of chronic myocarditis.

Elwood D. Wilson, Jackson, Mich.; Michigan College of Medicine and Surgery, Detroit 1897; member of the Michigan State Medical Society; aged 70; died, June 19, in the Addison Community Hospital of burns received when wires on a pole he was helping to erect in a hay field came in contact with power lines.

William Joseph Lynch, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1909; member of the Medical Society of the State of Pennsylvania; served during the World War; aged 53; died, June 24, in the Holy Name Hospital, Teaneck, N. J., of adenocarcinoma of the stomach.

Dennis Matthew Ryan, Ware, Mass.; University of Vermont College of Medicine, Burlington, 1884; member of the Massachusetts Medical Society; for many years member of the school committee; on the staff of the Mary Lane Hospital; aged 80; died, June 14, of coronary disease.

Amos Morris Peters ☉ Alexandria, La.; University of Nashville (Tenn.) Medical Department, 1902; served during the World War; at one time parish coroner; aged 63; formerly on the staff of the Baptist Hospital, where he died, June 19, of pyelitis and pneumonia.

William Moore Woodward ☉ McKeesport, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1891; past president of the McKeesport Academy of Medicine; on the staff of the McKeesport Hospital; aged 75; died, June 17, of chronic myocarditis.

Domenico Carantonio Mauro ☉ Mechanicville, N. Y.; Albany (N. Y.) Medical College, 1912; member of the board of education; aged 52; on the staffs of the Troy Hospital and the Leonard Hospital, where he died, June 14, following an operation for appendicitis.

Joseph J. Cobb, Berlin, N. H.; Medical School of Maine, Portland, 1881; member and past president of the New Hampshire Medical Society; formerly member of the board of education; for many years on the staff of St. Louis Hospital; aged 88; died, July 15.

Clarence Leonard Olson, McIntosh, S. D.; State University of Iowa College of Medicine, Iowa City, 1908; member of the South Dakota State Medical Association; aged 59; died, June 5, at the University Hospital, Minneapolis, of coronary sclerosis.

Howard Messner Ripley ☉ Kenosha, Wis.; Hahnemann Medical College and Hospital, Chicago, 1917; served during the World War; on the staffs of the Kenosha and St. Catherine's hospitals; aged 46; died, June 18, of coronary thrombosis.

Julius A. Klabs, Depew, N. Y.; Detroit College of Medicine, 1906; for many years health officer and school physician; aged 58; died, June 9, in the Buffalo General Hospital of *pneumophagus vulgaris*, bronchopneumonia, cystitis and septic splenitis.

Albert Prince Weaver, Philadelphia; Jefferson Medical College of Philadelphia, 1892; member of the Medical Society of the State of Pennsylvania; aged 82; died, June 26, in the Presbyterian Hospital, of arteriosclerosis and heart disease.

Harry S. Swope, Ashland, Ky.; Louisville Medical College, 1898; member of the Kentucky State Medical Association; past president of the Boyd County Medical Society; formerly county coroner; aged 65; died, June 23, of coronary occlusion.

Alexander Joseph Verdon, Ridgefield, N. J.; St. Louis University School of Medicine, 1934; police and school surgeon; aged 34; died, June 19, in St. Mary's Hospital, Hoboken, of diverticulitis of the sigmoid and intestinal obstruction.

Charles R. Russell, Des Moines, Iowa; Keokuk Medical College, 1898; member of the Iowa State Medical Society; formerly secretary of the Van Buren County Medical Society; aged 70; died, June 21, of cardiac decompensation.

Garrett Van der Veer Johnson, Lake City, Fla.; Albany (N. Y.) Medical College, 1896; veteran of the Spanish-American War; on the staff of the Veterans Administration Facility; aged 63; died, June 10, of coronary occlusion.

Tyrus Eugene Swan, Easton, Pa.; Kentucky School of Medicine, Louisville, 1889; past president of the Northampton County Medical Society; on the staff of the Easton Hospital; aged 79; died, May 28, of carcinoma of the nose.

Murray Lincoln Kaplun, New York; Hessische Ludwigs-Universität Medizinische Fakultät, Giessen, Hesse, Germany, 1923; served during the World War; aged 46; died, June 24, in the Memorial Hospital, of Hodgkins disease.

Andrew Jackson Heflin, Oberlin, La.; University of Nashville (Tenn.) Medical Department, 1906; member of the Louisiana State Medical Society; for many years parish coroner; aged 65; died, June 14, of coronary thrombosis.

Ralph Sumner Martin, Fredericktown, Pa.; University of Pittsburgh School of Medicine, 1912; aged 55; died, June 24, in the Hillview Sanitarium, Washington, of cerebral arteriosclerosis and acute adhesive pericarditis.

Anthony Kimmel Warner, Chicago; University of Maryland School of Medicine, Baltimore, 1885; on the staff of the American Hospital; aged 77; died, June 27, of cerebral hemorrhage and arteriosclerosis.

Percy Burdell Long, Copley, Ohio; Ohio Medical University, Columbus, 1898; member of the Ohio State Medical Association; served during the World War; aged 67; died, June 14, of cerebral hemorrhage.

Max Sonkin, New York; University and Bellevue Hospital Medical College, New York, 1917; member of the Medical Society of the State of New York; aged 47; died, June 13, of coronary thrombosis.

Sylvester Newton Mayberry, Enid, Okla.; St. Louis College of Physicians and Surgeons, 1893; president of the University Hospital Foundation; aged 73; died, June 22, of coronary embolism.

R. Berney McNeill, Jemison, Ala.; Memphis (Tenn.) Hospital Medical College, 1898; member of the Medical Association of the State of Alabama; aged 68; died, June 23, of angina pectoris.

Addison G. Swaney, Lees Summit, Mo.; University Medical College of Kansas City, Mo., 1906; formerly deputy coroner of Jackson County; aged 59; died, June 3, of hypertension and nephritis.

Harry Patrick Hall, Atlantic, Iowa; Drake University Medical Department, Des Moines, 1894; member of the Iowa State Medical Society; aged 69; died, June 24, of cerebral hemorrhage.

Luckey Andrew Jenkins, Birmingham, Ala.; Medical College of Alabama, Mobile, 1889; member of the Medical Association of the State of Alabama; aged 75; died, June 22, of myocarditis.

Ivan Dimiter Mishoff, Milwaukee; Rush Medical College, Chicago, 1889; an Affiliate Fellow of the American Medical Association; aged 83; died, June 20, of coronary thrombosis.

John Edward McGinnis, Green Bay, Wis.; Rush Medical College, Chicago, 1900; served during the World War; aged 69; died, June 12, in the Veterans Administration Facility, Hines, Ill.

Herbert E. Purcell, Charleston, S. C.; Howard University College of Medicine, Washington, D. C., 1894; aged 74; died, June 21, of cerebral hemorrhage, hypertension and arteriosclerosis.

Lavinia Dunn Lambert, Oakland, Calif.; University of Michigan Homeopathic Medical School, Ann Arbor, 1881; aged 93; died, June 22, of bronchopneumonia and mitral regurgitation.

Ambrose M. Mayfield, Montmorenci, Ind.; Kentucky School of Medicine, Louisville, 1894; aged 70; died, June 25, in St. Elizabeth Hospital, Lafayette, of coronary occlusion.

Clymer Defoor Jeffries, Williams, Ariz.; Atlanta (Ga.) College of Physicians and Surgeons, 1902; aged 60; died, June 22, in the Mercy Hospital, Flagstaff, of pulmonary edema.

Hugh McCulloh Sr., West Point, Ga.; Atlanta Medical College, 1895; member of the Medical Association of the State of Alabama; aged 67; died, June 16, of angina pectoris.

Richard McCord Hoffman, Orkney Springs, Va.; University of Virginia Department of Medicine, Charlottesville, 1907; aged 61, died, June 17, of coronary thrombosis.

Robert S. Linn, Detroit; Michigan College of Medicine and Surgery, Detroit, 1891; served during the Spanish-American War; aged 71; died, June 18, of cerebral hemorrhage.

Orville William Kimbell, Toledo, Ohio; Toledo Medical College, 1897; member of the Ohio State Medical Association; aged 68; died, June 9, of cerebral hemorrhage.

Alvah Vernon Mills, Newark, N. J.; University of Vermont College of Medicine, Burlington, 1905; aged 59; died, June 24, in Little Falls of coronary sclerosis.

David A. Yates, Avant, Okla.; Ensworth Medical College, St. Joseph, Mo., 1900; aged 62; died, April 2, of an embolus following an operation on the gallbladder.

William Henry Syme, Washington, D. C.; George Washington University School of Medicine, Washington, 1904; aged 70; died, June 6, in Hendersonville, N. C.

Charles H. Payette, Duluth, Minn.; Hospital College of Medicine, Louisville, Ky., 1898; aged 76; died, June 11, in St. Mary's Hospital, of bronchopneumonia.

Henry Sanford Liddle, Schenectady, N. Y.; Hahnemann Medical College and Hospital of Philadelphia, 1897; aged 70; died, June 28, of coronary disease.

J. Frank Williams, Roebuck, S. C.; Southern Medical College, Atlanta, Ga., 1888; aged 75; died, June 10, of bronchopneumonia and pulmonary emboli.

Nils Gabriel Rosen, Brooklyn; University and Bellevue Hospital Medical College, New York, 1918; aged 61; died, June 21, of cerebral hemorrhage.

Ellwood Matlack, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1886; aged 75; died, June 12, in Johnsville, Pa.

William B. May, Menands, N. Y.; University of Buffalo School of Medicine, 1896; aged 83; died, June 28, of coronary occlusion and arteriosclerosis.

Raymond B. Nutter, Enterprise, W. Va.; Louisville (Ky.) Medical College, 1905; aged 62; died, June 20, of carcinoma of the pancreas.

Edgar C. Hutchins, Greenville, Texas (licensed in Texas by years of practice); aged 63; died, June 21, of cerebral hemorrhage and pneumonia.

Percy Edwin Lilly, Kilmarnock, Va.; University of Maryland School of Medicine, Baltimore, 1901; aged 63; died, June 15, of angina pectoris.

Thomas B. Kerley, Simpson, Ill.; College of Physicians and Surgeons, Keokuk, Iowa, 1888; aged 76; died, June 27, of cerebral hemorrhage.

Perry K. Pratt, St. Joseph, Mich.; American Medical College, St. Louis, 1893; aged 74; died, June 12, of cerebral hemorrhage.

Joseph Edmond Le Sage, Montreal, Que., Canada; Laval University Faculty of Medicine, Quebec, 1895; aged 69; died, June 25.

Margaret H. Lister, Winfield, Kan.; John A. Creighton Medical College, Omaha, 1911; aged 67; died, June 12, of heart disease.

Matthew Alvin Lenton, Vineland, N. J.; Kentucky School of Medicine, 1904; aged 80; died, June 30, of arteriosclerosis.

Lyda McKendree, Bowling Green, Ohio; Toledo Medical College, 1892; aged 83; died, June 15, of arteriosclerosis.

Hugh R. Jeffrey, Morristown, Ohio; College of Physicians and Surgeons, Baltimore, 1893; aged 72; died, June 10.

Robert Hutchinson, Capron, Ill.; Rush Medical College, Chicago, 1876; aged 90; died, June 8, of pneumonia.

Thomas Herbert Sneath, Durham, Ont., Canada; Trinity Medical College, Toronto, 1895; died, May 27.

John Wesley Clubb, Blanford, Ind.; Louisville (Ky.) Medical College, 1884; aged 77; died, June 30.

Aldora J. Tyler, Clinton, Ill.; Woman's Medical College, Chicago, 1885; aged 79; died, June 7.

Josiah L. Barge, Gretna, La.; Atlanta (Ga.) Medical College, 1887; aged 82; died, May 22.

John S. Murphy, Sullivan, Ind.; (licensed in Indiana in 1897); aged 85; died in June.

Bureau of Investigation

SOME MISCELLANEOUS FRAUD ORDERS

United States Post Office Closes the Mails to Certain Medical Fakes

Fraud orders issued by the Post Office Department have frequently been the subject of extensive articles by the Bureau of Investigation in these pages of THE JOURNAL. Following are brief abstracts of some Fraud Orders not dealt with previously:

Alberta Studios—How to learn the secret formula for "pep" at the cost of a dime was the alluring promise held out by these "Studios," run by one A C Brckman of Buffalo. If one sent the dime he learned that "the secret" was simple "Natural Oats." In case the customer did not recognize the substance, he was told that it was "the kind of oats horses get," and further, "the reason horses are given oats is to make them PEPPY." If one needed further convincing, he was told that "the natural goodness in oats has given me EXTRA PEP—I am sure it will give you that PEPPY FEELING, the same as myself and as horses." If one wanted to feel as peppy as Mr. Bachman or as horses, he was told to "take a ½ gallon of NATURAL OATS, soak in 2 gallons of distilled water 44 hours bring to a boil not more than 10 minutes, keep covered while boiling, cool, strain, pressing excess from oats, put in bottles and keep corked." Finally he was told that if he would drink a wineglassful (presumably of the expressed liquid) after each meal and keep up the good work "for a week or two" he would "see the different PEPPY person" the stuff had made of him. But the skeptical Post Office Department consulted expert medical authorities, who pointed out that following the directions for taking this "oat brew" would provide the taker with only about 20 units of vitamin B₁ daily, whereas an adult requires about 250 units daily, and that the only minerals in natural oats whose absence from the diet is likely to cause mineral deficiency disorders are those which are not water soluble, consequently this "oat brew," from which the directions require the straining of all pulp, would not furnish the user with any therapeutically significant amounts of the important minerals. It was further shown that loss of "pep" may be due to many conditions on which the use of this "oat brew" would have no effect whatever. Brckman also sold a booklet, "Whatever You Desire Can Be Yours," which all inclusive promise was obviously impossible of fulfillment. Altogether his schemes were found to justify the issuing of a fraud order against his business, and this was done on Oct 14, 1940.

Allen Health Food Company—This concern, located at Keansburg, N J, had an A W Caskey as manager. It did business by mail, selling "Enerjol" for the restoration of lost youthful vigor. Caskey was found to be an electrician without medical training, yet he promoted his "cure" as "A NEW SCIENTIFIC DISCOVERY OF A VITAMIN WHICH IS CALLED THE 'ANTISTERILITY VITAMIN,'" adding that "it comes under the head of Vitamin E, and has to do with fertility, youthful vigor, and all the other desirable things we mortals covet!" Government chemists reported that Enerjol consisted of small globular capsules or "perles" containing vitamin E in the form of wheat germ oil. Expert witnesses testified at the government hearing that the amount of vitamin E was too small to remedy a deficiency thereof. Also they pointed out that neither vitamin E nor any other treatment will correct all cases of sterility or sexual decline. On Aug 15, 1940 the Post Office banned this business from the mails on the ground that it was fraudulent.

Anatone Company—This New York concern used the mails to sell "Anatone" under what the Post Office Department declared were false and fraudulent representations that it would completely overcome all forms of constipation, prevent the recurrence thereof (except where there is "another" alleged "unbalancing of normal routine") and produce "normal, natural" bowel movements, and that the product is different from ordinary methods of treating constipation, does not involve the use of drugs and produces no injurious effects. Government chemists reported that Anatone was a colorless, sticky material to be inserted into the rectum by means of a nozzle tube and that it consisted essentially of water, glycerin, boric acid and small amounts of gelatin and a gum. Expert medical testimony was produced to show that such a mixture and method will not bring about a natural bowel evacuation or eliminate the basic causes of constipation. Hence it would not and could not offset improper dietary, lack of exercise, deleterious hygienic conditions, abnormal nervous or glandular states, the use of opiates and other factors in constipation. Further, despite the promoters' claims to the contrary, Anatone did contain drugs, did act as a cathartic, would irritate the lower bowel and its use could be harmful and in some cases dangerous. As its sale was held to be a fraudulent means of obtaining money through the mails, a fraud order was issued against the Anatone Company, Anatone Company Production Department and their officers and agents as such on Dec 18, 1939.

Harris Research Bureau—This Phoenix, Ariz., concern was run by a P C Harris who sold through the mails the alleged answers to 650 questions, representing that his replies were valuable and correct. These "650 opportunities for employment and financial independence" were obtainable for \$1. The customer was told that he could, in turn, go into the business of selling the answers to other customers, making 75 cents on each deal and paying the Harris concern 25 cents. The Post Office investigation disclosed that the Harris circulars contained a long jumbled list of questions on unrelated subjects under several headings which were allegedly answered in the material supplied to customers. Under the heading "How to do These Things" were listed such subjects as "Get Sleep," "Remove Warts," "Help Babies Sleep" and "Remove Surplus Fat." Under the heading "How to Make" were "Small Pox Remedy," "Hair Oil," "Freckle Lotions," "Eczema Ointment," "Psoriasis Remedy," "For Tooth Decay Prevention," "Remedy for Baldness," "Itch or Ringworm Remedy," "Treat Sugar Diabetes" and some other things. Another title, "How To

Do These Things," covered such subjects as "Grip Flesh," "For Arthritis," "For Pellagra," "Stop Hiccoughs," "For Athletic Feet," "For High Blood Pressure" and "How To Prevent Headaches." The Post Office found that careful examination of the questions and answers disclosed that for the most part the replies were valueless, unreliable and in a considerable number of instances false. Particularly false, according to the expert testimony of a physician at the hearing of the case, were the answers furnished to the large number of medical questions propounded and did not afford customers proper information for treating the various disorders involved. It was further emphasized that in many of the diseases mentioned self treatment would be dangerous and might even result in loss of life. In some cases the advice given was utterly ridiculous. The patient with appendicitis, for instance, was told to "stand on head so poison runs out of appendix." Such worthless "information" as this and some other replies was held to defraud the customers and consequently the Harris Research Bureau was debarred from the mails by a Post Office fraud order issued on Oct 23, 1940.

Lanac Chemical Company—On July 25, 1940 the Post Office debarred this Chicago concern from the mails on the ground that its "Lanac Compound" was being sold through that means under fraudulent pretenses, representations and promises as a remedy for varicose ulcers and "terrible sores" on the body. Government chemists reported that it was a dark brown ointment containing balsam of Peru, ichthammol and about 8 per cent of bismuth (as oxygallate), with a slight vanilla odor. Expert medical testimony showed that this mixture would have little value in treating chronic leg sores, especially those caused or complicated by varicose veins. The concern neither put up any defense nor sent a representative to the hearing. Another government agency, the Federal Trade Commission, reported in February 1938 that it had prevailed on the Lanac Chemical Company, Chicago, trading under the name Dr. Latham Chemical Company, to promise to drop the term "Dr" in its name, implying that a licensed physician was associated with the business, and to cease representing that the ointment was a competent treatment and cure for varicose ulcers and had been used in a prominent clinic.

Philipp Wong—From Cambridge, Mass., this person, a Chinese, sold by mail a product that he called "Soft Corns Valuable" and promoted it as a cure for corns and skin diseases, including even such serious ones as psoriasis, cancer and those resulting from syphilis. In his come on literature Wong quickly claimed to "guarantee all kinds corns CURE." Those up to five years growth could be "cured" for \$2 and those over ten and up to thirty years development would require \$25 worth of the treatment. Besides, "35 years old skin trouble don't cost so much"—but just how much, was not stated—and Wong promised it would be gone in six months. Another misrepresentation was that the nostrum had been recognized by the United States government. Federal chemists reported that it consisted essentially of sulfides of sodium, iron and copper. On Feb 2, 1940 the Post Office Department debarred the scheme from the mails on the ground that it was a fraud. In October 1935 a Boston newspaper reported that Wong had been warned by the Federal Trade Commission that he would be prosecuted unless he ceased advertising his "Soft Corns Valuable" as being good for cancer.

Saenger Concern—This Shreveport, La., outfit was run by one A D Saenger, who did business by mail under a number of "Saenger" trade styles that gave the impression that he was in the drug business. His nostrums, sold under the "Saenger" brand, included "Sarsaparilla Skin and Blood Purifier," "Wonder Wine for Women" and "Kidney Root." The Skin and Blood Purifier, advertised for syphilitic conditions, tumors, scrofula, catarrh, rheumatism and some other things, was found by government chemists to consist essentially of water sugar, sarsaparilla, alcohol (41 per cent), potassium iodide (58 grains per fluidounce), licorice and other plant extractives. The Wonder Wine for Women, claimed to be "a purely vegetable compound highly recommended for the treatment of all female weaknesses and disorders," was reported to be 18.4 per cent alcohol with sugar and water, plus yuburnum and other plant extracts. The Kidney Root, according to one claim, "Positively relieves all kidney, bladder and liver trouble." It was found to be a light brown liquid containing 10.5 per cent of alcohol, and in each fluidounce 17.8 grains of methenamine, 26.1 grains of sodium sulfate and ¼ grain of sodium salicylate, with sugar and water. The Post Office produced sufficient evidence that the Saenger business constituted a scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises and on Jan 5, 1940 issued a fraud order against the concern but not against the A D Saenger back of it.

Zulema Morafma Gelo—From Mexico City this person advertised that for stated sums of money she would relieve the sufferer of any disease, all fortune and unfavorable influences. In one of her advertisements, all printed in Spanish in a San Antonio, Texas, paper, she claimed to be "The potential clairvoyant of world fame, who prophesied the European War, and who predicts another war, tells the past, present and future, a spiritualist, mental (hypnotic) suggestions, graphology, matters pertaining to astrology, love, business, psychological advice, repels unfavorable influences in all business. Highly scientific in palm reading. Consult her at Honduras 41, Department 8, Mexico, D F." Those who "bit" were requested to furnish certain information concerning their illness or difficulty and remit \$2 by international money order for advice on overcoming the condition. One customer, who stated only that he had "terrible pains in the stomach" and cramps in the legs was told to take camomile tea every morning for the stomach trouble and resort to a printed "Prayer to the Watersprites" which Zulema Gelo supplied. Expert medical testimony was produced to show that, though camomile tea may have a slight stimulant and irritant effect on the lining of the stomach, it would have no practical value in the treatment of any serious disease of the stomach, and that an irritant tea in cases of stomach ulcers and cancer, for instance, would undoubtedly increase the painful symptoms. The testimony further pointed out that persons who relied on the advice furnished by this advertiser might even lose their lives through failure to obtain proper medical treatment. The Post Office accordingly debarred the business from the United States mails by means of a fraud order issued on Nov 23, 1940.

SURGERY VS. INJECTION TREATMENT OF VARICOSE VEINS

To the Editor:—A communication to the editor of THE JOURNAL, May 25, 1940, page 2139, by Isaak Ludwig discussing the paper of Dean and Dulin suggests the many inconsistencies in the present discussion and treatment of varicose veins. In their paper, Dean and Dulin state that there are more fatalities than are reported with the injection treatment of varicose veins. They state that they use the high ligation plus the injection treatment in these cases. In the same paper they cite Westerbom's statistics on the comparative mortality rates with the various types of treatment, which show a mortality of 0.26 per cent with surgical treatment alone, 0.33 per cent with high ligation plus the injection treatment and only 0.036 per cent with the injection treatment alone.

These statistics, which I am convinced will check favorably with the average reliable statistics, show a ten times greater mortality rate with high ligation plus retrograde injection than with the injection treatment alone.

Kettel says, in his cited paper, that the extremely low mortality rate among patients treated by injections alone can be further reduced by proper precautions. With regard to the high ligation and retrograde injection treatment, he states that the mortality rate rises from 0.5 per cent to 1 per cent and cites Bernsten, Kilbourne, Laqua, Reichel and others. He writes "The majority of authors [Meissen, Kilbourne, Fraenkel, Gruca, Baur, Vigyozo] reject the combined treatment of high ligation and injection."

Probststein calls attention, in his cited paper, to 120,000 injections of varicose veins in a series of 15,000 consecutive cases, observed by Sicard and Gangier, without a single mortality.

Silverman writes: "A search of the literature has revealed a total of only 19 cases of embolism following in hundreds of thousands of cases."

Kilbourne reports that he did not have a single fatality in his clinic in 20,000 injections of varicose veins. He calls attention to the thrombus formed above the ligation, which is an important source of fatal embolism. Other authors have called attention to this fact. McCallig and Heyerdale (A Basic Understanding of Varicose Veins, THE JOURNAL, July 13, 1940, page 97) have well shown this graphically.

In 1922 we began the injection treatment of varicose veins at the University of Minnesota (Hayes, J. M.: Treatment of Varicose Veins, *Journal-Lancet* 45:12 [Jan. 1] 1925). Since then I have either done or supervised more than 30,000 injections without a single mortality. During this time, only 1 patient had to be hospitalized. We did not see evidence of a single embolism. Seldom do we see a patient who is not able to continue his occupation without interruption during this treatment.

In 1930 Dr. Bell's department at the University of Minnesota sectioned veins which we had removed a few days after injection. The sections show the resulting thrombus intimately interwoven with the intima of the vein. This is in striking contrast with the thrombus otherwise produced. The thrombus frequently formed above the ligation is the type that does result in fatal embolism.

McPheters and de Takats call attention to the fact that ligation at the end of the great saphenous vein would prevent thrombus above the ligation. This is true but apparently is not always done.

We have used practically every sclerosing solution suggested for this purpose since Linscr first instituted this method of treatment by injecting mercury bichloride.

In 1922 we began cautiously using mercury bichloride as the sclerosing solution. At first we accepted only patients with severely infected ulcers. These patients had all been rejected for surgery.

The injection treatment gradually replaced surgery not only in the cases of severe involvement but also in the mild, ordinary varicose veins. We made more than 2,000 injections of mercury bichloride before less toxic solutions were suggested. We had no serious results.

Previously, while at the Mayo Clinic, I worked with Dr. Sistrunk, who was doing much of the surgery of varicose veins at the clinic at that time. He employed most of the methods suggested at that time but for the most part did the Mayo stripping removal of the veins.

Many surgeons did multiple ligations, hoping to cure varicose veins in this way. The latter method caused the collapse of the vein following the operation, but frequently in a short period the veins were filled through communicating branches and appeared much as they did originally. Today we frequently see the same sort of recurrences following the high ligation.

Surgery was abandoned several years ago in the treatment of varicose veins because of the high morbidity, mortality and expense of this method when compared with the injection treatment.

In 1921 at the University of Minnesota it was evident that a large proportion of patients were not having their varicose veins treated. The large number of old, sloughing varicose ulcers was evidence of this. A few years after we began the injection treatment of varicose veins, varicose ulcers were rare.

It is true that some patients do respond more readily to high ligation and retrograde injection, but these patients are comparatively few. In the average case there is little difference in the time element with the two methods of treatment. And the inconvenience to the patient is far less with the injection treatment alone. In a large number of cases nearly as many injections are necessary after the high ligation is made. Many who do the high ligation are tempted to inject a large amount of solution at the time of ligation. With the injection treatment alone, a small amount of solution may be injected to make sure that the patient is not allergic to this particular solution. I am certain that this is one source of the serious results with the high ligation and retrograde injection method.

After observing and employing all suggested methods for the past several years, I now follow the procedure I published in *Minnesota Medicine* (13:564 [Aug.] 1930). For several years now I have injected varicose veins wherever they appear on the thigh. The results here are as good as elsewhere.

There are recurrences with this method as with all other methods, but patients do not hesitate to return to have these recurrences treated with the injection method as they do when treated surgically. We have patients return after a year or two for a few injections and continue on their job without interruption. We have followed some of these patients for from fifteen to nineteen years. Some have returned several times for a few injections but are well pleased with the results.

If only a small amount of solution is introduced at the first injection, to make sure that the patient is not allergic or has an idiosyncrasy to the solution, and, if strict asepsis is observed, little difficulty should be encountered with this method.

It has been suggested that not all the bad results have been reported in the high ligation and retrograde injection method. I am certain that this is true. In one hospital in Minneapolis there have been 2 fatalities, and another serious result, which I am sure have not been reported. These patients were all treated by well trained surgeons.

Men highly trained in the high ligation and retrograde injection method may be skilful or fortunate enough to operate with-

out bad results, but I am sure that in the hands of the average medical man the mortality rate will agree favorably with Westerborn's statistics.

Dr. de Takats has shown theoretically why injection treatment of varicose veins in cases of deep thrombophlebitis will not give good results.

Varicose veins are not functioning veins. Wherever they exist they are merely pools of stagnant blood. This blood gradually seeps through the wall of the dilated vein into the surrounding tissues. This readily creates a condition susceptible of infection. Slight trauma causes a breaking down of the local tissues, resulting in a varicose ulcer.

We have injected and thrombosed these veins for many years with no bad results. While improvement is slow, we do get good results. Our chief precaution here is to avoid giving these patients injections during acute thrombophlebitis. We usually wait from three to six months after an acute condition. An embolus may result from the acute thrombophlebitis. If injected during this time, such an embolus may be credited to the operator.

Dr. Ochstner and his associates (Treatment of Thrombophlebitis by Novocain Block of the Sympathetics, *Surgery* 5:491 [April] 1939) have popularized the paravertebral injection in cases in which ulcers exist in the presence of an old thrombophlebitis. Our experience with this method is quite limited, but in a few cases we have had excellent results. In refractory cases of old thrombophlebitis in the presence of swelling, edema and painful ulcers, this injection has proved efficacious.

It is sometimes surprising how the pain ceases, the swelling and edema subside and the ulcer sometimes clears up without further treatment. I hail this procedure as a promising aid in these troublesome cases.

J. M. HAYES, M.D., Minneapolis.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

CHICAGO, Feb. 16-17, 1942. Council on Medical Education and Hospitals, Sec., Dr. William D. Cutter, 535 North Dearborn Street, Chicago.

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in *THE JOURNAL*, August 9, page 473.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Montgomery, June 16-18. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ARKANSAS: * *Medical*. Little Rock, Nov. 6-7. Sec., Dr. D. L. Owens, Harrison. *Eclectic*. Little Rock, Nov. 6. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

CALIFORNIA: Oral examination (required when reciprocity application is based on a state certificate or license issued ten or more years before filing application in California), San Francisco, Oct. 1. *Written*. Sacramento, Oct. 20-23. Sec., Dr. Charles B. Pinkham, 1020 N St., Sacramento.

COLORADO: * *Examination*. Denver, Oct. 7. *Endorsement*. Denver, Oct. 8-10. Sec., Dr. George R. Buck, 831 Republic Bldg., Denver.

CONNECTICUT: *Medical*. Examination. Hartford, Nov. 11-12. *Endorsement*. Hartford, Nov. 25. Sec., Dr. Creighton Barker, 258 Church St., New Haven. *Homeopathic*. Derby, Nov. 11-12. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

DISTRICT OF COLUMBIA: * Washington, Nov. 10-11. Sec., Dr. George C. Ruhland, 6150 East Municipal Bldg., Washington.

FLORIDA: * Jacksonville, Nov. 24-25. Sec., Dr. William M. Rowlett, Box 786, Tampa.

GEORGIA: Atlanta, Oct. 14-15. Sec., State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta.

IDAHO: Boise, Oct. 7. Dir., Bureau of Occupational License, Mr. Walter Curtis, 355 State Capitol Bldg., Boise.

ILLINOIS: Chicago, Oct. 14-16. Supt. of Registration, Mr. Lucien A. File, Department of Registration and Education, Springfield.

INDIANA: Indianapolis, June 16-18. Sec., Board of Registration and Examination, Dr. J. W. Bowers, 301 State House, Indianapolis.

KANSAS: Kansas City, Sept. 23-24. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

KENTUCKY: Louisville, Dec. 6-10. Sec., Dr. A. T. McCormack, 620 S. Third St., Louisville.

MARYLAND: *Medical*. Baltimore, Dec. 6-12. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. *Eclectic*. Baltimore, Dec. 9-10. Sec., Dr. John A. Evans, 111 W. 4th St., Baltimore.

MICHIGAN: * Lansing, Oct. 15-17. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 203 Hollister Bldg., Lansing.

MINNESOTA: * Minneapolis, Oct. 21-23. Sec., Dr. J. F. Du Bois, 230 Lowry Medical Arts Bldg., St. Paul.

MISSISSIPPI: *Reciprocity*. Jackson, December. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MONTANA: Helena, Oct. 6-8. Sec., Dr. Otto G. Klein, First National Bank Bldg., Helena.

NEW HAMPSHIRE: Concord, Sept. 11-12. Sec., Board of Registration in Medicine, Dr. T. P. Burroughs, State House, Concord.

NEW JERSEY: Trenton, Oct. 21-22. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: Santa Fe, Oct. 13-14. Sec., Dr. Le Grand Ward, 135 Sena Plaza, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, Sept. 15-18. Chief, Bureau of Professional Examinations, Mr. Herbert J. Hamilton, State Education Department, 315 Education Bldg., Albany.

NORTH CAROLINA: *Endorsement*. December. Sec., Dr. W. D. James, Hamlet.

NORTH DAKOTA: Grand Forks, Jan. 6-9. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OKLAHOMA: * *Reciprocity*. Oklahoma City, Dec. 10. Sec., Dr. James D. Osborn, Jr., Frederick.

TEXAS: Austin, Nov. 17-19. Sec., Dr. T. J. Crowe, 918 Texas Bank Bldg., Dallas.

VERMONT: Burlington, Feb. 10-12. Sec., Board of Medical Registration, Dr. F. J. Lawliss, Richford.

VIRGINIA: Richmond, Dec. 9-12. Sec., Dr. J. W. Preston, 30½ Franklin Road, Roanoke.

WISCONSIN: * Madison, Jan. 13-15. Sec., Dr. H. W. Shutter, 425 E. Wisconsin Ave., Milwaukee.

WYOMING: Cheyenne, Oct. 6-7. Sec., Dr. M. C. Keith, State Capitol Bldg., Cheyenne.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ARIZONA: Tucson, Sept. 16. Sec., Mr. Franklin E. Roach, Science Hall, University of Arizona, Tucson.

COLORADO: Denver, Sept. 10-11. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

CONNECTICUT: Oct. 11. Address State Board of Healing Arts, 1945 Yale Station, New Haven.

DISTRICT OF COLUMBIA: Washington, Oct. 20-21. Sec., Dr. George C. Ruhland, 203 District Bldg., Washington.

FLORIDA: DeLand, No. 1. Final date for filing application is Oct. 17. Sec., Professor J. F. Conn, John B. Stetson University, DeLand.

IOWA: Des Moines, Oct. 14. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines.

MINNESOTA: Minneapolis, Oct. 7-8. Sec., Dr. J. C. McKinley, 126 Millard Hall, University of Minnesota, Minneapolis.

NEBRASKA: Lincoln, Oct. 7-8. Dir., Bureau of Examining Boards, Mrs. Jeannette Crawford, 1009 State Capitol Bldg., Lincoln.

OREGON: Portland, Nov. 1. Final date for filing application is Oct. 15. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

RHODE ISLAND: Providence, Aug. 20. Chief, Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

SOUTH DAKOTA: Aberdeen, Dec. 5-6. Sec., Dr. G. M. Evans, Yankton.

WISCONSIN: Madison, Sept. 20. Sec., Professor Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee.

District of Columbia May Report

The District of Columbia Board of Examiners in Medicine and Osteopathy reports the written examination for medical licensure held at Washington, May 12-13, 1941. The examination covered 9 subjects and included 60 questions. An average of 75 per cent was required to pass. Six physicians were licensed to practice medicine by reciprocity and 6 physicians so licensed on endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
George Washington University School of Medicine.....(1934)	84.5		84.5
(1938) 84.5, (1939) 82.5, 83.6, 88.5, (1940)* 77, 77, 79, 83.5, 89.3			
Georgetown University School of Medicine.....(1939)	79.1		
81.8, 81.8, (1940)* 84.2, 88.3			
Howard University College of Medicine.....(1940)	80.8*		
The School of Medicine of the Division of the Biological Sciences.....(1938)	83.8		
Johns Hopkins.....	81		
Tufts College.....	86.5		
Washington U.....	83.1		
Columbia Unit.....	77.1		
Jefferson Medical College of Philadelphia.....(1932)	80.1		
Queen's University Faculty of Medicine.....(1932)	85.5		

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with

* Licenses have not been issued.

Alaska Reciprocity Report

The Alaska Board of Medical Examiners reports 1 physician licensed to practice medicine by reciprocity and 1 physician so licensed on endorsement of credentials of the National Board of Medical Examiners from March 25 through May 7. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year	
		Grad.	with
Columbia Univ. College of Physicians and Surgeons..	(1937)	Washington	
School	LICENSED BY ENDORSEMENT	Year	
		Grad.	with
University of Minnesota Medical School.....	(1940)		

Montana March-April Report

The Board of Medical Examiners of Montana reports the written examination for medical licensure held at Helena, March 31-April 1, 1941. The examination covered 10 subjects and included 50 questions. An average of 75 per cent was required to pass. Six candidates were examined, 5 of whom passed and 1 failed. Nine physicians were licensed to practice medicine by reciprocity and 1 physician so licensed on endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

School	PASSED	Year	
		Grad.	Per Cent
College of Medical Evangelists.....	(1941)		86.5*
Northwestern University Medical School.....	(1931)		89.7
University of Tennessee College of Medicine.....	(1933)		83.2
University of Manitoba Faculty of Medicine.....	(1940)		87.9
Universität Zürich Medizinische Fakultät.....	(1936)		86.6
School	FAILED	Year	
		Grad.	with
University of Arkansas School of Medicine.....	(1907)		
School	LICENSED BY RECIPROCITY	Year	
		Grad.	with
Northwestern University Medical School.....	(1910), (1926)	N. Dakota,	
Rush Medical College.....	(1938)	Minnesota	
The School of Medicine of the Division of the Bio-logical Sciences.....	(1937)	Wyoming	
University of Minnesota Medical School.....	(1931)	Minnesota	
University of Nebraska College of Medicine.....	(1940)	Nebraska	
Ohio State University College of Medicine.....	(1929)	Ohio	
University of Texas School of Medicine.....	(1924)	Texas	
School	LICENSED BY ENDORSEMENT	Year	
		Grad.	with
Tufts College Medical School.....	(1930)		

* This applicant has completed four years' medical work and will receive the M.D. degree on completion of internship. License has not been issued.

Minnesota April Report

The Minnesota State Board of Medical Examiners reports the written examination for medical licensure held at Minneapolis, April 15-17, 1941. The examination covered 12 subjects and included 60 questions. An average of 75 per cent was required to pass. Sixty-five candidates were examined, all of whom passed. One physician was licensed to practice medicine by reciprocity and 2 physicians so licensed on endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

School	PASSED	Year	
		Grad.	Per Cent
Yale University School of Medicine.....	(1938)		88.6

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Alleged Premature Discharge of Patient from Hospital and Abandonment of Treatment.—Milton Meiselman, a boy of 8 years at the time, was kicked in the left knee in November 1931. Shortly afterward he complained of pain in the leg, and his father called the defendant physician Schoolnik, who after examining the child stated that he was unable to treat the condition (diagnosed shortly thereafter as osteomyelitis) and suggested that the defendant physician Koster be summoned, which was done. On Koster's direction the boy was taken to the Crown Heights Hospital, Inc., a hospital conducted for profit. At that time the child was "desperately ill and required a blood transfusion." Koster operated on both legs and encased them in plaster casts. After the boy had been in the hospital eighteen weeks he was discharged, over the father's protest, allegedly because the parents had paid only about \$350 of the hospital bill of approximately \$1,000 that had been incurred to that date. At that time the patient was not cured: he had a "high temperature," he had casts on both legs and "both legs had open wounds through which pus was draining through windows" in the casts. The father, according to his testimony, was informed then by both defendant physicians that there was no need to transfer the child to a charitable hospital and that Schoolnik, under Koster's supervision, would give proper care to the boy at home. It was necessary to put dressings on the wounds about once a week, and this was done for five weeks by Schoolnik, who, it was alleged, on no occasion after the patient's discharge from the hospital consulted Koster. During this time the child suffered intense pain, his legs became increasingly worse, and on occasions Schoolnik, while attempting to remove parts of the cast, caused lacerations of the legs. Finally at Schoolnik's request the boy was sent to Kings County Hospital. When he was admitted to that institution, according to the testimony of Dr. Degenhardt, the physician who supervised his treatment there, both of his legs were in casts from the knee joints down, and he had a temperature of 101 F. On removing the casts Dr. Degenhardt found that the right ankle over the middle malleolus had a healed sinus, that there had been a long deep wound over the entire length of the left tibia, that there was a sinus over the lower end of the left femur and that there were large open wounds which were dirty and had thick white crusts about them. There was a moderate amount of thick, tenacious, purulent discharge from the region of the left tibia. Roentgenograms, subsequently taken, showed destruction of the proximal two thirds of the left tibia. The condition was then diagnosed as chronic osteomyelitis of the right tibia, left tibia and femur. The infectious process and

drainage continued until about four weeks after the boy's admission to the Kings County Hospital, at which time the improvement was so far advanced that Dr. Degenhardt put new casts, without drainage windows, on both legs from the toes to the upper third of both thighs. The next four years the boy was hospitalized and treated at the Kings County Hospital and in another institution and when finally discharged he was "severely crippled, walked with a limp, and one of his legs was stiff." He brought an action by his guardian ad litem against the Crown Heights Hospital, Inc., and the two defendant physicians, Schoolnik and Koster, for negligence and malpractice in treating him and for abandoning his case before he was cured. The trial court, even before the evidence on his behalf was concluded, dismissed the case, and its action was affirmed by the supreme court, appellate division, second department, New York. An appeal was then perfected to the Court of Appeals of New York.

On the record, said the Court of Appeals, as it stood when the trial court dismissed the action, the plaintiff had made out a prima facie case on the issue of malpractice against Schoolnik and Koster and of wilful abandonment of his case against the hospital and Koster. Sufficient evidence was presented to warrant a jury in awarding damages on those charges. At least, the jury might have found that the defendants had prematurely and wilfully abandoned the case while the patient was desperately ill and before he was cured without giving information or advice as to subsequent treatment or of the desperate and dangerous condition and character of the disease, all of which led to aggravation of his condition and illness. Common sense and ordinary experience and knowledge, such as is possessed by laymen, without the aid of medical expert evidence, might properly have suggested to the jury that the condition of the boy at the time that he was left without hospitalization and abandoned by the defendants was not compatible with skilful treatment. That the plaintiff's parents were misled by the conduct of the physicians to the child's detriment is inferable from the facts adduced. Ordinarily, to furnish a basis for the determination by a jury of unskilful practice and medical treatment by physicians, expert medical opinion evidence is required, when the subject matter to be inquired about is presumed not to be within common knowledge and experience and when legal inference predominates over statement of fact. However, when ordinary jurymen from their own experience and observation may draw their own conclusions, the opinion of experts is unnecessary.

At the trial, in connection with the testimony of Dr. Degenhardt, who had treated the boy at Kings County Hospital, the trial court, on the general objection that they were "incompetent, irrelevant and immaterial," refused to admit in evidence records of that hospital concerning the boy. The court permitted Dr. Degenhardt to refer to the records to refresh his recollection but excluded the records themselves, saying "You cannot have records when you have the witness present in court. That is the best evidence." No objection, said the Court of Appeals, was made to the admission of the records on the ground that no proper foundation had been laid for their admission or on other grounds than the general grounds stated. The blanket exclusion of the records on the grounds of incompetency, irrelevancy and immateriality left the plaintiff without proof on what may have been essential features of his case and relieved him of proceeding further with proof of facts essential to warrant their admission under the New York statute, which under stated circumstances authorizes the admission in evidence of entries and memorandums made in the regular course of any business, profession or calling. As the case stood, the records should have been admitted in evidence, and their exclusion was erroneous.

At the trial, the plaintiff called as an expert witness a Dr. Colmers, who had been licensed to practice in New York since 1936, had received his preliminary and medical education in Germany, had engaged for ten years in educational research after his graduation, thereafter for more than six years had been an assistant in the surgical clinic and chief surgeon of a hospital in Germany which had six hundred beds and thereafter was surgeon for ten more years on the staff of another hospital in Germany, specializing in general surgery. Since

coming to the United States he had been connected with a stated hospital in New York. While practicing in Germany, according to his testimony, he became familiar with the treatment of osteomyelitis because he had personally treated hundreds of such cases and had also become familiar with the treatment of that disease throughout the world by reading literature on the subject. The trial court refused to permit him to testify as an expert on the sole ground that he was not competent to testify as to the proper practice in the United States in 1932, the year in which the defendants had treated and cared for the plaintiff. The nature of osteomyelitis, said the Court of Appeals, and its cause and probable effect were proper subjects for testimony of a competent medical witness. A showing was made that the witness was skilled in the profession to which the subject relates. No precise rule has been formulated and applied as to the exact manner in which such skill and experience must be acquired. Long observation and actual experience, though without actual study of the subject, qualify a witness as an expert in a subject. Likewise, a physician may qualify himself from study of the subject alone. The extent of the expert's qualifications may always be considered by a jury in determining the weight to be given to his testimony. Residence alone neither bars a physician from testifying as an expert nor qualifies him so to do. The question of the qualification of a witness to testify as an expert is for the determination of the trial court in its reasonable discretion, which discretion, when exercised, is not open to review unless in deciding the question the trial court has made a serious mistake, has committed an error of law or has abused its discretion. In the opinion of the Court of Appeals it was an error of law for the trial court to hold that Dr. Colmers was disqualified to testify at all as an expert. Whether he was qualified to express an opinion as to whether the medical and surgical treatment of the patient by the defendants was in accord with commonly accepted medical practice, on the record before it, the court was not called on to decide.

For the reasons stated, judgment dismissing the action was reversed and a new trial was ordered.—*Miscelman v. Crown Heights Hospital, Inc.*, 34 N. E. (2d) 367 (N. Y., 1941).

- Washington State Medical Association, Seattle, Aug. 24-26. Dr. Verron W. Spiekard, 1308 Fourth Ave., Seattle, Secretary.
- Wisconsin, State Medical Society of, Madison, Sept. 10-12. Mr. G. B. Larson, 110 East Main St., Madison, Assistant Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1931 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Hemoconcentration and Shock.—Moon studied hemoconcentration incident to experimental shock, intestinal obstruction, pulmonary edema, burns, bile peritonitis, various extracts of tissue, poison, drug and chemical agents and other conditions (anaphylaxis) affecting the circulation. More than 300 animals (dogs, cats, guinea pigs, rabbits, rats and monkeys) were used. The agents (venoms, bacterial toxins, cholic salts, histamine, bacterial products, peptone, barbitol and paraldehyde) and the conditions mentioned produced hemoconcentration regularly in each animal and each species. When recovery followed, the blood returned to its normal concentration. When death resulted, the engorgement and stasis of blood in capillaries and venules, ecchymoses, serous effusions and edema in soft tissues indicated endothelial damage in extensive visceral areas. These effects are related to the syndrome of shock. Capillary atony results in anoxia of the tissues, and anoxia will cause capillary atony. This is a most important and significant relationship. These two factors are reciprocal; either of them, operating alone, will bring the other into action. Thus the mechanism is self perpetuating and operates as a vicious circle. Its progress, if uninterrupted, leads to irreversible changes and death. The physiologic mechanism which regulates the movement of fluid between the blood and the tissues depends essentially on a normal semipermeable endothelium. Capillary walls so damaged that they allow whole plasma to escape cannot maintain an effective differential between the composition of the intravascular and extravascular fluids. Such a condition disarranges the relationship between water balance and absorption. Serious hemorrhage produces clinical manifestations of shock. Frequently its effects and those of anesthesia and trauma are combined. Any loss of blood or fluid contributes toward shock, and its contributory effect is proportional to the amount of blood and/or fluid lost. Hemoconcentration will distinguish between the uncomplicated effects of hemorrhage and those of shock. Shock is not limited to extensive trauma, surgery or burns. The same type of circulatory failure develops from poisoning with drugs and chemicals, abdominal emergencies, irradiation and serum sickness, metabolic intoxications and unusually severe infections. Hemoconcentration is the earliest detectable sign of threatened circulatory deficiency of capillary origin. It is as ominous as a decline in blood pressure. But hemoconcentration occurs early when compensation is effective, while hypotension indicates that compensation has failed and that death is imminent. Heretofore hemoconcentration has not been recognized, understood or utilized by physicians in their clinical studies.

Effects of Iron on Hemoglobin Formation.—Fowler and Barer gave iron and ammonium citrates or reduced iron to 25 nurses and young adults healthy except for a mild anemia. These preparations produced an increase in the blood hemoglobin, which reached a peak at the end of from ten to twelve weeks. Following this peak there was a gradual reduction in the hemoglobin level regardless of whether or not therapy was continued for only the sixty days or throughout the period of observation. The increase in hemoglobin, the peak and subsequent reduction were similar in patients with mild grades of anemia and in individuals with low normal hemoglobins, although in the latter group the hemoglobin fell to the pretreatment level, whereas in the former it remained elevated but at a level below the point of maximal response. The results suggest a stimulating action of iron on hemoglobin formation in addition to its action as replacement therapy.

Fat Tolerance Tests in Psoriasis.—There is a growing tendency to attribute psoriasis to a generalized disturbance in fat metabolism. Le Winn and Zugerman studied the fat tolerance of 10 patients with this disease. Changes in the total cholesterol of whole blood were used as an index of the degree of alteration of the blood lipid level. The patients showed no significant changes as compared with 13 nonpsoriatic subjects acting as controls. The incidence of psoriasis in conditions such as hypothyroidism, diabetes mellitus, xanthelasma, nephrosis and pregnancy, exhibiting hypercholesterolemia or hyperlipemia, was reviewed. Only pregnancy was found to have a relationship to psoriasis, and its influence was beneficial. The amelioration of psoriasis in starvation, low fat intake and pregnancy and in individuals receiving adrenal cortex extract or hypophyseal corticotrophic hormone is, in the authors' opinion, the result of the mobilization of fats and lipoids from all the tissues. This removes from the skin substances whose presence is irritating. Psoriasis is a disease due to conditions existing locally in the skin. A generalized disturbance in fat metabolism may possibly contribute to such local conditions.

Vitamin K Administered During Labor.—Beck and his associates studied the clotting activity on the first, second and fourth days of life of 200 infants. Vitamin K was given during labor to alternate mothers. The clotting activity of the 100 control infants on the first day of life was approximately 70 per cent of that observed in normal adults. A physiologic fall in prothrombin usually occurred on the second day. This fall at times may reach dangerously low levels. Evidence of hemorrhage was present in 50 per cent of the infants whose clotting activity fell below 35 per cent of normal. By the fourth day clotting values tended to approach the first day levels and usually reach the first day level by the sixth day. A clotting activity in newborn infants approaching that of the normal adult may be obtained on the first day by the prophylactic administration of vitamin K to the mother during labor. Vitamin K administered to the mother during labor also prevents the physiologic fall in prothrombin values. Only 1 infant among the 100 whose mothers received vitamin K during labor had a clotting value on the fourth day of 38 per cent of the normal adult value. Vitamin K given during labor and ante partum should prevent some of the hemorrhages which occur in newborn infants. Only 5, or 0.5 per cent, of 1,022 infants whose mothers received vitamin K showed any evidence of hemorrhage in contrast with 21, or 2 per cent, of 1,037 control cases. Accordingly, vitamin K should be valuable in reducing the incidence of hemorrhage in all newborn infants, and especially so in premature infants or after long labor and operative procedures.

Sickle Cell Anemia in Pregnancy.—The report of Kobak and his co-workers on 6 cases of sickle cell anemia occurring during pregnancy brings the total to 17. The anemia is believed to be a familial disease transmitted by both sexes as a dominant mendelian characteristic. It is seen only in the younger age groups; most persons with active signs of the disease die (either from the effects of the anemia or from intercurrent diseases) before they are 30 years of age. This is suggested by the ages of the 17 patients with sickle cell anemia during pregnancy; the youngest patient was 18 and the oldest was 30, the average age being 22.4 years. Only 3 of 15 became multiparas. The

viable stage of gestation was reached by 13 of the 17 mothers. There were 5 deaths; 4 necropsies were held. Abdominal crisis was the terminal cause of 2, multiple thrombi and complicating pulmonary embolus with multiple terminal infarcts of 1, puerperal sepsis of 1 and hepatosplenomegaly and parenchymatous degeneration of various organs, including the heart, of the remaining patient. Certain clinical symptoms are frequently observed. The patients are usually thin and underdeveloped. Complaints consist of frequent attacks of respiratory infections, joint and muscle pains, vague abdominal pains with nausea and vomiting, occasional fever, ulcers of the legs, jaundice and cardiorespiratory symptoms associated with a severe anemia. The disease is characterized by remissions and exacerbations. During pregnancy, hypertensive or preeclamptic toxemia develops frequently in these patients. Roentgenologically osteoporosis of the long bones is commonly seen, while the skull shows increased thickness of the calvarium and loss of continuity of the outer table, and the marrow cavity is replaced by altered bone formations. The final diagnosis rests on the blood picture. During acute episodes there is a profound anemia; the erythrocyte count is usually below 2,500,000 with a corresponding decrease in hemoglobin. A leukocytosis far in excess of that expected in pregnancy is seen. Most of the erythrocytes are sickle shaped. The prognosis is grave, and most of the patients die before the age of 30. Pregnancy apparently has an unfavorable effect; 5 of the 15 whose clinical history is on record did not survive the pregnancy. At least 2 additional mothers have died sometime subsequent to the publication of their case reports. The prognosis for the fetus in utero is also unfavorable. Available data of 15 mothers reveal that 5 had one or more abortions. These mothers had thirty-seven pregnancies, of which only twenty-five were carried to viability. Nineteen of the viable babies were born alive, whereas 6 were macerated stillbirths. The blood of at least 8 of the babies born alive had sickled erythrocytes. Follow-up studies may have enlarged this number. Intensive antianemic therapy and multiple blood transfusions have had a measure of success. The authors believe the improvement to be only temporary. The treatment of any intercurrent disorder and general supportive measures (rest and a diet high in calory and vitamin content) aid improvement.

Fatality Rate of Pneumococcal Pneumonia.—Flippin and his associates discuss factors which influence the prognosis of pneumonia. Their study is based on the results among 800 adult pneumococcal pneumonia patients, the mortality among whom was 10 per cent. Fifty-four and two-tenths per cent of the patients were 40 or more years of age. Among the fatalities 83.7 per cent represented patients in this age group. The mortality rate was 3.5 per cent for patients 12 to 39 years of age and 15.4 per cent in the higher age group. This significant

difference is largely a result of the higher incidence of associated diseases in older patients. The age of the patient is probably the most important single factor in the prognosis of this disease. Treatment during the first four days of the disease, with a mortality rate of 5.6 per cent, was received by 65.3 per cent of the patients, which represented 36.2 per cent of the deaths. Among the patients treated after the fourth day of illness there was a mortality rate of 18.4 per cent, and 63.8 per cent of the fatalities were among these patients. The first three types of pneumococci gave the highest mortality rate (12.2 per cent); 17.4 per cent were type III infections (often in elderly and debilitated patients) with a mortality rate of 20 per cent as compared to 7 and 10.5 per cent for types I and II respectively. The type of pneumococcal pneumonia has a direct bearing on prognosis. The incidence of bacteremia for all the patients was 12 per cent, whereas 40 per cent of the patients who died had positive blood stream infections. The fatality rate for the bacteremic patients was 32.3 per cent. Complications developed in 48 patients. They were mild in 35 and none of these died. The mortality rate was 53.8 per cent for the remaining 13 with severe complications. Associated disease was present in 264 patients. Race and sex appeared to be of little or no prognostic significance. The widespread distribution and administration of sulfonamide therapy in pneumonia will have a definite influence on hospital practice, as more patients will be treated at home and only the severely ill will be sent to a hospital. This will undoubtedly result in a reduction in the general mortality but an increase in hospital fatality rates. The use of the drugs for many types of infections will probably increase drug sensitivity, and the problem of chemotherapeutic toxicity may become more acute. Other factors which have a bearing on the prognosis are the geographic location, rural or urban community, the economic status, occupational hazards, the presence of unsuspected or untreated disease, the time of seeking medical aid and overindulgence in alcohol and the habits of a patient.

Treatment of Barbiturate Intoxication.—Anderson treated 20 patients for barbiturate poisoning; all of them took the drug with suicidal intent. Picrotoxin was used for all but 6 of the patients, in whom the intoxication was mild and responded to other methods of treatment. Study shows that there is a considerable margin of safety in the use of barbiturates. No extreme intoxications occurred with quantities less than twelve times the usual dosage. The interval between the ingestion of the drug and the beginning of treatment is extremely important. Even large doses may not cause serious consequences if gastric lavage is carried out within a few hours. Patients with bulbar paralysis, hyperpyrexia, tachycardia and shallow respirations die unless some powerful stimulant is employed immediately. Because of depressed respiratory function and the resulting atelectasis, the first signs of pneumonia must be detected and sulfapyridine therapy instituted at once. Three of the author's patients with extensive pneumonia and severe barbiturate poisoning recovered. In severe cases ordinary stimulants, caffeine, strychnine and nikethamide, are ineffective. Solutions of dextrose and sodium chloride intravenously, supplemented in some instances by injections of salyrgan, have an important place in therapy. When cyanosis is present, oxygen by the inhalation method is helpful. Metrazol was used for 2 patients; 1 of them recovered with no other treatment, and in the other picrotoxin was substituted but the patient died. Picrotoxin is the drug of choice in treating barbiturate intoxication. It is a powerful stimulant, and the author has observed no ill effects from its use. For best results it should be instituted promptly if the reflexes are abolished and should be given intravenously at the rate of approximately 1 cc., or 3 mg., per minute until the corneal reflexes reappear and the patient responds to painful stimuli. Thereafter it should be repeated every one or two hours in sufficient dosage to keep the corneal reflexes active. Whenever the patient is allowed to lapse into a severe depression for several hours his chances of recovery are greatly lessened. Giant bullas occurred in pressure areas of several patients. The dosage of picrotoxin was decreased deliberately in 1 or 2 instances, until it was ruled out as the cause. The author believes that their occurrence is reported for the first time. The giant bullous lesions varied in size

from 2.5 to 10 cm. Severe peripheral neuritis developed in 1 patient and similar, though less severe, symptoms in another. This emphasizes the importance of nutritional deficiency. Many of the patients are psychoneurotic and there is little point in preventing their suicide unless the proper psychiatric and social treatment is furnished afterward. Some are normal mentally, but their living conditions are so poor that they are driven to destroy themselves. Investigation by a social worker, followed by encouragement and the necessary aid, may restore some of the latter patients to a useful place in the community.

Pressor Activity of Kidneys.—Williams and his associates produced unilateral renal ischemia in dogs and rats, prepared fractions from such kidneys by extraction with a solution of sodium chloride or by precipitation with alcohol and determined their pressor action. The results were as follows: 1. The extracts from ischemic kidneys of dogs usually had a distinctly greater pressor effect than similar extracts from normal kidneys of the same animal. When the degree of ischemia was so severe as to induce necrosis, the abnormal kidney had less pressor effect than the normal organ. 2. The extracts from normal rat kidneys had as much or more pressor effect when compared with those of their ischemic kidneys, provided the fractions were tested soon after being prepared. 3. One important similarity was displayed by kidneys from both rats and dogs: on standing, the extracts from normal kidneys usually became less pressor and those from the ischemic organs tended to become more pressor. 4. When enzymatic processes were reduced to a minimum by rapid freezing and desiccation of the kidneys while frozen, the extracts in many instances had practically no pressor effect. However, usually a well defined pressor action developed if such inactive, freshly prepared extracts were allowed to stand. The authors believe that the divergent results of the pressor activity of normal and ischemic kidneys obtained by previous investigators were apparently due to (1) difference in the species of animals used as a source of kidneys and (2) changes occurring in the activity of the extracts after preparation. The apparent renin content of an extract is extremely variable; it may increase or decrease with time or even be absent under certain conditions.

Primary Bacillus Friedländer Pneumonia.—Perlman and Bullowa state that among 2,450 cases of pneumonia there were 37, or 1.5 per cent, caused by the Friedländer bacillus; in 29 the causative organism was Bacillus Friedländer A and in 8 B. Friedländer B. Friedländer pneumonia occurs predominantly in older people and it occurs much more frequently in men than in women; 32 of the 37 patients were men. Of 29 patients with Friedländer A pneumonia, 28 were men. The incidence

of bacteremia averages about 70 per cent. In the present series (A and B forms) it was 32.5 per cent; 7 of those with Friedländer A pneumonia and 5 of those with Friedländer B pneumonia. The mortality among the patients with Friedländer A and B pneumonia did not differ significantly, being 86 and 75 per cent, respectively, from that reported by other workers. There appears to be no relationship between bacteremia and mortality; in fact, the authors' patients without bacteremia had a somewhat higher mortality than those with bacteremia. Of 23 patients with Friedländer A pneumonia, 6 of whom had bacteremia, treated with sulfanilamide or sulfapyridine or serum alone or combined with chemotherapy 20 died, and of 6 untreated patients, 1 of whom had bacteremia, 5 died. All the 13 patients treated with serum alone, 3 with rabbit and 10 with horse serum, died. Of 6 treated patients with Friedländer B pneumonia, 4 of whom had bacteremia, 5 died, and of 2 untreated patients the 1 without bacteremia died. Serum, sulfanilamide (or sulfapyridine) or the combined therapy seemed ineffectual in treating patients with B. Friedländer pneumonia. One hopeful trend could be seen among the patients with Friedländer A pneumonia, for 3 of 8 patients treated with the drug recovered.

Sulfanilamide and Sulfapyridine for Endocarditis.—According to Friedman, it is of utmost importance in treating bacterial endocarditis chemotherapeutically to know whether the drugs act directly on the invading micro-organism or act by increasing tissue resistance against invasion. If sulfanilamide or sulfapyridine is to be effective, the drug must not only be able to destroy or definitely inhibit the growth of *Streptococcus viridans* without the physical aid of living tissue but also be able to penetrate the fibrin-platelet barrier characteristic of the disease in sufficient concentration to affect its results. If a drug's effectiveness depends on the potentiation of living tissue resistance or if it is unable to penetrate this barrier which protects the organisms and isolates them from living tissue, it will probably be of no value in bacterial endocarditis. The author carried out a series of experiments to determine (1) the degree of penetrability of both drugs through fibrin-platelet masses, (2) their in vitro effects on three strains of *Streptococcus viridans*, (3) effects in vivo on animals harboring these strains of *Str. viridans* but with the complete isolation of the micro-organisms from living tissue, (4) the effects of prolonged administration of both drugs on infected animals and (5) the actual results of the drugs administered to patients suffering with subacute endocarditis due to *Str. viridans*. Sulfanilamide or sulfapyridine was not able to penetrate easily the fibrin-platelet mass containing *Str. viridans*. The production of a focus of protected growth of *Str. viridans* in the abdomen of the rabbit with the concomitant parenteral administration of sulfapyridine or sulfanilamide to the animal showed that the two drugs were no more effective against *Str. viridans* in vivo than they were in vitro; but if the inoculum was small and its growth was not allowed to progress too far, the effectiveness of either drug, particularly sulfapyridine, was such that it was supposed that living tissue would have furnished no further aid in destroying the organism. It may be that the powerful effect of these drugs when given parenterally to animals infected with the hemolytic streptococcus, as contrasted with their possible equivocal action on the same organism in the test tube, is due to the fact that the bacterial invasion in the body is relatively slight and the number of bacteria per unit of invaded tissue is far less than that present in various test tube experiments. Despite the effectiveness of the drugs on *Str. viridans* when they were placed in immediate contact with a small inoculum, if as little as six hours were allowed to elapse between contact of either of the drugs and the initial inoculum of *Str. viridans* their bactericidal action, despite concentrations, was nil. The experimental production of a fibrin-platelet mass infected with the organism but separated from living tissue by means of a porcelain filter capsule led to a persistence of infection despite the quantity and duration of administration of either drug. The effectiveness of the drugs was negligible in 12 patients with subacute endocarditis caused by *Str. viridans* treated with sulfanilamide or sulfapyridine or both. Three of the patients received intensive heparin therapy in conjunction with sulfapyridine or sulfanilamide, and the results were equally negative. Although Friedman, Hamburger and Katz were the first to

suggest and use heparin in subacute endocarditis and although favorable results have been reported by Kelson and White, it is now believed by them that its action either alone or with sulfapyridine is of no real value.

History of Human Poliomyelitis.—Sabin and Ward performed necropsies in 11 fatal cases of poliomyelitis and examined various tissues to determine whether the virus was predominantly distributed in any one system. The results show that the virus is so distributed in certain regions of the nervous system and in the alimentary tract. This knowledge permits the following reevaluation of the various prevailing hypotheses of the disease in human beings: 1. The absence of demonstrable virus in the olfactory bulbs and anterior perforated substance indicates that in man the olfactory pathway need not be affected. 2. The absence of infective virus in the nasal mucosa suggests that this is not the site of virus multiplication and dissemination.

3. The virus was not present in the salivary glands, indicating that the saliva is not an elimination route. 4. The positive results with the tonsils and pharyngeal mucosa are probably due to the pharyngeal tissue rather than to the tonsils. 5. In the alimentary tract the virus is present not only in the contents but also in the washed walls of various parts of the tract, including the pharynx, ileum and occasionally the colon. 6. Infection of the walls of the alimentary tract appears to be the result neither of primary localization nor the port of entry. 7. Its distribution in the central nervous system is limited to certain areas and is not as indiscriminately disseminated as viruses (e. g., equine encephalomyelitis) which can invade through the blood vessels or those (e. g., rabies) which are capable of extensive centrifugal spread. 8. In the absence of evidence of any appreciable centrifugal spread to peripheral collections of nerve cells, the demonstration of virus in the abdominal sympathetic ganglions of 1 case suggests one of the possible routes of virus progression in certain instances. The pattern of virus distribution in human poliomyelitis, according to the study, points to almost the entire alimentary tract as the primary site of attack by the virus and supports in no way the concepts involving either the olfactory pathway or the respiratory tract. The distribution also militates against the cutaneous route, although it is conceivable that occasional infection through the broken skin may be possible. There appears to be much similarity between this picture of human poliomyelitis and that of Theiler's spontaneous mouse encephalomyelitis or poliomyelitis, in which Olitsky demonstrated that the virus is carried in the intestinal tract of many normal mice, although paralysis develops in only 1 of 2,000 to 5,000 mice. The subsequent demonstration by Theiler and Gard and by Olitsky that the infectious agent is also present in the washed intestinal wall and that this is the most probable origin of the virus in the intestinal contents brings out a most remarkable analogy between the two diseases.

Acute Appendicitis and Pseudoappendicitis.—Langmann states that of 19 rheumatic children admitted to the hospital with the tentative diagnosis of acute appendicitis 10 were subjected to a laparotomy, and acute appendicitis was found in 4 (of minimal degree in 2). In a fifth patient a normal appendix (except for Oxyuris) was removed and no satisfactory explanation for the abdominal signs was found. The remaining 14 instances were considered to be rheumatic pseudoappendicitis. Of the 19 children, 5 gave a history of previous rheumatic episode and had muscle or joint pains at the time of or just before admission. The abdominal symptoms and signs were often not sufficient to differentiate between rheumatic pseudoappendicitis and acute appendicitis. The erythrocyte sedimentation rate should prove of distinct aid in differential diagnosis. Acute appendicitis developed in 2 other children, in 1 in the middle of and in the other toward the end of an acute attack of rheumatic fever. The abnormal appendixes showed no

pathologic changes that were characteristic of rheumatic disease. If after a short period of observation there is a reasonable doubt as to the existence of acute appendicitis, laparotomy should be done. If the condition proves to be rheumatic no harm is done by the operation, whereas procrastination in a case of acute appendicitis may result in death.

Tuberculin Reaction.—Furcolow and his associates tested members of several different population groups with gradually increasing concentrations of tuberculin. Thus all persons of a particular group were tested initially with an exceedingly dilute concentration of tuberculin, and those who did not react were retested four days later with a more concentrated solution. This procedure was continued step by step until all persons reacted or until the largest dose (ranging from $\frac{1}{400}$ billionth of a milligram to 1 mg. in 0.1 cc. of physiologic solution of sodium chloride) was used. The tests were performed by the intracutaneous method. Institutional groups were studied, as any general population group presents obvious difficulties when repeated testing is necessary. The nontuberculous groups consisted of 553 white children from 6 to 19 years of age residing in an orphanage in Ohio, 200 adults in the institution and 116 infants and young children, residents of two founding homes, ranging in age from birth to 6 years. No roentgen evidence of pulmonary tuberculosis was found in the children of either home. Roentgen studies were not made of the adults of these institutions. The tuberculous and contact groups consisted of 60 children who were patients in a hospital for active tuberculosis, 46 children in a preventorium for inactive cases and children who had had intimate contact with tuberculosis, 101 children in an antituberculosis camp, about 60 per cent of whom had a history of probable contact with active tuberculosis, and the entire adult population (468 white and Negro patients) of a hospital for the treatment of active tuberculosis. The children ranged in age from birth to 14 years and the adults from 15 to 70 years. The clinical diagnoses of the adults varied from minimal to far advanced tuberculosis. Less than 10 per cent of this group were reported to have had a previous tuberculin test. No proved active tuberculosis was found among either the adults or the children of the orphanage. Another group of 499 adults from 15 to 60 years of age, inmates of an institution for the insane, was tested. More than 10 per cent of this group had active tuberculosis and therefore the remaining patients were considered as contacts. The results of the quantitative testing of the 553 children in the orphanage show approximately 20 per cent positive reactions at the level of the usual first testing dose of purified protein derivative, 50 per cent at the level of the second testing dose and 96 per cent at the largest dose, 1 mg. of tuberculin. Family histories of 309 children showed that 61 had a history of contact, and these children were much more sensitive to tuberculin than were those of the entire orphanage group. Conversely, the children who had no history of contact were less sensitive. The positive response to the seventh test dose (one one-hundred thousandth mg. in 0.1 cc. of tuberculin) was 6.5 per cent among the children without a history of contact in contrast to 77 per cent of those with such a history. As to the infants and children of the two founding homes, although there were no reactors to the smaller doses of tuberculin, most of the infants, including those less than 6 months of age, reacted to the larger doses. Sensitivity to tuberculin increased with age; the curve for the children from 4 to 6 years of age approached the curve for children

from 6 to 19 years of age who had no known history of contact. The children (in the tuberculosis and contact groups) in the antituberculosis camp were more sensitive than those of the orphanage group. The children of the preventorium had a higher percentage of reactors to the lower test doses. This sensitivity to the lower doses was even more marked among the children with active tuberculosis, approximately 95 per cent of whom reacted at a level of dosage equivalent to the usual first testing dose of purified protein derivative and all of them reacted at a dosage level five times as concentrated. In contrast, only 20 per cent of the orphanage group and 42 per cent of the children in the antituberculosis camp reacted to this dose. The curves for adults in the tuberculosis and contact groups were similar to the curves for the tuberculous children. This is further evidence that reactions to small doses of tuberculin, or cutaneous hypersensitivity, occur with great regularity in persons with active tuberculosis. The adults were slightly less sensitive than the children; for example, 84 per cent of the adults had reactions to the seventh dose and 99.6 per cent to the eighth as compared to 93 per cent and 100 per cent, respectively, of the children. The 499 patients in the hospital for the insane were not as sensitive to tuberculin as were active cases of tuberculosis but were far more sensitive than the children in the orphanage, none of whom had active tuberculosis.

Irradiation of Carcinoma of Cervix.—Stone and Robinson describe their method of treating carcinoma of the uterine cervix and the reasons for the adoption of the new technic. If the lesion is small and well localized, the first treatment with radium is given immediately after the biopsy, to be followed

by the complete course. If the growth is in stage I or stage II (Schmitz) and the patient is a good operative risk, a Wertheim operation is performed. Otherwise a course of roentgen therapy follows the course of radium. If the growth is bulky and extensive, the course of roentgen treatments is given first and then followed in from two to six weeks by radium therapy. The purpose of roentgen therapy first is to decrease the size of the lesion so that radium can be applied more effectively. Radium is the principal medium. The beam of roentgen rays is not aimed at the cervix but at all the probable regions of extension and metastasis. The lymph nodes of from 30 to 50 per cent of patients with "operable" lesions are involved. From 10 to 20 per cent of patients with small local lesions, without parametrial involvement, have metastases in the lymph nodes. Therefore patients with large and small lesions should have roentgen irradiation, unless a radical Wertheim operation is to be performed. About 90 per cent of lymphatic involvement occurs in the primary nodes, which consequently must be included in the regions irradiated. These primary nodes are (1) the hypogastric beside the hypogastric artery just below the bifurcation of the common iliac artery, (2) the obturator on the obturator nerve near the femoral ring, (3) the iliac nodes along the external iliac artery at and below the bifurcation of the common iliac artery, (4) the sacral nodes on the anterior surface of the sacrum and (5) the parametrial nodes, including the ureteral node. Direct extension of the cancer into the parametrium and vagina may occur, and irradiation must include these structures. Accurate aiming of the beam is as important as selecting the cutaneous fields and the amount of radiation to be given. The position of each treatment must be carefully checked by the physician. Technicians should not be given this responsibility. The amount of radiation given should be all that the normal tissues can tolerate. Six fields produce the best internal distribution of the radiation. Five year survivals of patients treated by a combination of radium and roentgen rays from a 200 kilovolt unit indicate that the growth of the cancer growth is retarded or destroyed.

Chronic Ulcerative Colitis.—Rankin and Johnston point out that, since ulcerative colitis may be initiated or an exacerbation may follow infection of the upper part of the respiratory tract or any disease, trauma or local irritation, the presence of the offending organism as part of the intestinal flora, dangerous only in the face of some physiologic abnormality, is suggested. The disease may superimpose itself on the damaging effects of a dysentery or on the result of some injurious irritant or trauma.

Usually (in 95 per cent) the disease begins in the rectum and progresses upward across the transverse colon, often reaching the cecum. Segmental involvement is observed in about 5 per cent of cases. If proliferation and repair fail to keep pace with tissue necrosis and destruction, perforation resulting in generalized peritonitis or localized abscess formation follows. The diagnosis of ulcerative colitis is rarely difficult except in the earliest phase of the disease before the general grayish yellow appearance of the patient, progressive increase in the number of daily stools and digital, proctoscopic and roentgen signs have become established. Treatment is primarily medical, but about 15 per cent of patients present complications for which immediate surgical intervention is indicated. The first group consists of perforation, hemorrhage, abscess or fistula formation, acute fulminating disease and acute intestinal obstruction, and the second group comprises advanced visceral degeneration and infection, polyposis and malignant degeneration. Chemotherapy and continuous duodenal drainage have altered the original conception of treating perforation so that now the method advised by Ochsner in the treatment of appendical peritonitis seems often advisable. The indirect surgical attack has no place in the treatment of hemorrhage. Abscess formation, whether abdominal or perirectal, should be drained surgically. Conservatism must be predominant. For the acute fulminating case surgical drainage, ileostomy, has been urged. Surgical decompression is the only means to relieve intestinal obstruction. Elective surgical intervention is reserved for those patients for whom sepsis, polyposis or malignant disease endanger life. The condition of patients with malignant disease and polyps indicating resection is usually better than that of those with visceral degeneration and sepsis. Rehabilitation is therefore less difficult and will require a shorter interval. Ileostomy is the most simple and satisfactory procedure for deflecting the fecal stream as a therapeutic measure or as an initial step in the radical removal of the large intestine. When further surgical intervention is considered, a sufficient length of time must be permitted for adequate rehabilitation. If colectomy is advised, the time element should depend entirely on the patient's surgical tolerance. Colectomy, exteriorization of that part of the involved colon, ileocolostomy and ileosigmoidostomy have no guaranty of retarding the disease and must be reserved for only a few carefully selected cases. Colectomy is a formidable procedure. The single right McBurney ileostomy with the inverted distal stump dropped into the abdomen will greatly simplify this procedure and minimize wound infection or peritonitis. For 20 patients multiple stage procedures have been used with 1 exception. Following operation this patient suffered a dehiscence of his wound and died in the second week from peritonitis. One other patient died from a pulmonary embolism following a graded colectomy. An adequate period of readjustment following ileostomy cannot be too strongly emphasized. The 19 patients underwent forty-three operations, and all of them recovered and have had a satisfactory convalescence.

Radical Operation for Varicose Veins and Ulcer.—There is no unanimity of opinion regarding the treatment of severe varicose veins and varicosities complicated by leg ulcers. Mahorner outlines a radical operative procedure for these cases which consists of excision of a lenticular area of subcutaneous tissue containing the varicosities and the deep fascia, exposing the muscles and thus tying all communicating veins in this area. When pigmentation or subcutaneous scarring is heavy or when the ulcer does not heal because of subcutaneous scarring, such areas are excised down to the muscle, and a split skin graft is used to replace it. In certain cases of severe varicose veins it is essential not only to ligate the saphenous and its tributaries high at the fossa ovalis but also to resect segments in the lower third of the thigh or upper third of the leg. The radical operation is indicated for the most severe type of varicose veins with ulcers due to multiple leaks from the deep to the superficial veins through communicating veins in the leg. The author emphasizes the point that the static pressure is the same in varicose as in normal veins but that the kinetic pressure or pressure in the actively moving extremity is much less in normal veins than in varicose veins. The

Trendelenburg test and its doubly positive reaction may indicate whether the retrograde flow in varicose veins occurs through communicating veins and the main opening of the saphenous, but it does not localize the leaking communicating veins. It gives the information that the incompetent communicating veins are somewhere below the main opening of the saphenous, but the Mahorner-Ochsner test definitely localizes the level of the leaks in the communicating veins and it can thus be of great value in indicating the operative procedure essential for the disturbed physiologic function in severe varicose veins and ulcers.

- Phenol and Tetanus Antitoxin in Experimental Tetanus.**—Thompson and Friedman carried out controlled experiments on dogs in an attempt to determine the value of phenol alone or combined with antitoxin. The method advocated by Suvansa was investigated and the authors assumed that his maximal dose of 40 cc. was for treating a young, well developed man of 150 pounds with a severe case of tetanus. From this they deduced the intrathecal dose of 0.57 cc. per kilogram of body weight of a 1:400 phenol solution in physiologic solution of sodium chloride. They desired to use a dose of tetanus toxin that would kill the dog regardless of the amount

of tetanus antitoxin administered. Abel and Chalian found that if 100 dog lethal doses of tetanus toxin was injected intravenously and that if six hours elapsed, no amount of antitoxin could save the animal. This amount was used, since the authors felt that by so doing they could tell whether phenol alone or with tetanus antitoxin was of any benefit in extreme tetanus. Experiments show that the intrathecal administration of phenol to dogs given intravenously 100 lethal doses of a tetanus toxin known to kill healthy dogs within twenty-five to twenty-six hours will not prevent the animal's death. Their death seemed to be hastened by the additional damage to the central nervous system or by the lowered resistance to distemper which phenol apparently produces. However, the administration of tetanus antitoxin in sufficient amounts saves dogs when given within six hours of a similar dose of toxin. The lethal dose for dogs of a 1 per cent solution of phenol was found to lie between 0.3 and 0.35 Gm. per kilogram of body weight when given intravenously. The damage to the kidneys and liver was directly proportional to the amount of phenol given. The 1 per cent solution of phenol given intravenously and simultaneously with 100 dog lethal doses of tetanus toxin through opposite veins did not alter the progress of the tetanus, and the bioassays did not reveal any detoxifying effect of the phenol. If the phenol in the dosage used was given simultaneously with 10 dog lethal doses of tetanus toxin through opposite veins, it still did not alter the progress of the tetanus and neither did the bioassays reveal any detoxifying effect of the phenol. The authors point out that the common preservatives used in tetanus antitoxin are definite irritants to the central nervous system and that tetanus antitoxin containing these preservatives should not be used intrathecally in the treatment of tetanus. Dogs given 100 dog lethal doses of tetanus toxin intravenously were saved when they were given at six hours from one hundred and eighty-two to two hundred times the neutralizing dose of tetanus antitoxin. Dogs given 100 dog lethal doses of tetanus toxin were saved when they were given at seven hours three hundred times the neutralizing dose of tetanus antitoxin, although signs of tetanus developed. Evidently in seven hours a portion of the toxin was so irreversibly fixed that it could not be neutralized by the antitoxin.

Eclampsia and Post eclamptic Hypertension.—Chesley and Somers present a follow-up study of 167 eclamptic women encountered among 42,476 deliveries at the Margaret Hague Maternity Hospital. Of these, 20 are known to be dead, 141 were reexamined in 1940, and an additional 4 had been followed for at least a year before they were lost track of. Only 2 patients have had no follow-up. There were 12 immediate maternal deaths. The maternal mortality among the 114 primiparas, who made up 68 per cent of the cases, was 4.4 per cent and among the 55 multiparas it was 12.7 per cent. The total loss of babies (abortions, stillbirths, neonatal deaths and undelivered babies of mothers dying of antepartum eclampsia) was 33.5 per cent. There were 8 sets of twins; 2 women were admitted twice, giving 177 babies. Of these 118 were discharged alive, 47 were stillborn and 12 were neonatal deaths. As the pregnancy progresses and the fetus becomes larger, the rate of survival increases. Much of the adverse effect of eclampsia on the baby seems to lie in premature delivery. Yet most of the deaths are not neonatal deaths; the majority, 79.6 per cent, of the babies lost are stillborn. Hence it seems that, the older the fetus, the more resistant it is to whatever intrauterine factor is so often lethal. Of 144 babies born after the thirty-fifth week of gestation 28, or 19.4 per cent, were stillborn. Of the 116 born alive 4, or 3.45 per cent, died. Assuming the death rate to remain constant, delivery at the thirty-fifth week would have saved 23 infants if the eclampsia could have been foreseen. In an analysis of the results of carrying a toxic patient to secure an older and heavier baby with consequent lower neonatal mortality, it appears that when delivery is delayed more than three days after the first convulsion 57.2 per cent of the fetuses die in utero; delivery within three days shows a stillbirth rate of 25.8 per cent. In postpartum eclampsia only 2.2 per cent of the fetuses are stillborn. The duration of toxemia, regardless of the time of convulsions, has a definite effect on fetal survival, the death rate increasing as the toxemia

is prolonged. Of 29 patients carried for more than four weeks with toxemia, 62 per cent failed to have living babies. The degree of prematurity also played a part. The fetal mortality increases with the severity of the toxemia. The mortality rate rises as the blood pressure or proteinuria increases. The relation between the number of convulsions and fetal death is nearly linear. There were 8 remote deaths; 1 was caused by a septic abortion eighteen months after the eclamptic pregnancy, 2 by pulmonary tuberculosis at respectively four and one-half months and three and one-half years post partum, and 5 died of cardiovascular causes from seven months to three and a half years after the eclamptic delivery. None of these 8 remote deaths occurred in private patients. At follow-up (from one to eight years) the incidence of hypertension among the 147 surviving women was 17.5 per cent. This is significantly greater than that among the general female population, after correction is made for age distributions. The incidence of proteinuria of significant degree was 2.6 per cent at follow-up. Renal function, as measured by the urea clearance and urinary specific gravity, was in the normal range in at least 97 per cent of the patients at follow-up. The majority of the living hypertensive women had significant eyeground changes, half had cardiac enlargement and 8 had signs and symptoms of cardiac insufficiency. Analysis of factors contributing to the persistence of hypertension shows that in general high blood pressure is more likely to be found at follow-up if there are antecedent renal or vascular disease, high blood pressure in pregnancy, advanced age of the patient, many previous children, and the eclampsia and obesity long and severe. Not one of these factors is so decisive in conditioning remote hypertension as is recurring toxemia subsequent to the eclampsia. The recurrent rate of toxemia in pregnancies after eclampsia was found to be 47 per cent. The foregoing factors which favor the persistence of hypertension favor in even greater degree the recurrence of toxemia. Advising a post eclamptic patient against future pregnancies would seem to be justified by the recurrent rate of toxemia, with a consequent eightfold potential increase in permanent hypertension if the pregnancy is toxic.

Raynaud's Symptoms.—Johnson presents the histories, physical and laboratory observations, treatment and course of 22 patients with Raynaud's symptoms. All the patients presented Raynaud's symptoms in the fingers, and 11 had similar symptoms in the toes, but in no case did the symptoms occur in the toes without the fingers being affected. In only 3 instances were emotional upsets a frequent cause, and in these surgery on the sympathetic failed to produce any improvement as judged by recurrence and frequency and severity of attacks. Associated diseases were comparatively common: 2 patients had syphilis, 13 a mild secondary anemia, 2 a severe anemia, 3 stiffness of the finger joints, scleroderma, ulcers, loss of tissue, and loss of fingernails and 2 had sclerodactylia. Treatment consists of relief of mental anxiety, improvement of anemia, treatment of any specific disease and surgical treatment by operations on the sympathetic nervous system. The main reasons for the apparent lack of progress in knowledge of the symptom complex of Raynaud's disease are (1) differences of opinion as to whether Raynaud's disease exists as a clinical entity, (2) failure to understand the nature of the vascular changes and (3) differences of opinion regarding treatment. Certain data from the present study throw light on the nature of the vascular changes during attacks and further bear out the opinion that the changes observed in the extremities are merely symptoms of some more fundamental disease. The study does not completely bear out the generally accepted view that blanching of fingers or toes during an attack is caused by active peripheral vascular constriction. The blanching may be caused in part by a vasodilatation in the palmar arch and a passive collapse of the vessels in the fingers from an inadequate amount of blood and blood pressure to keep them open; that is, the blood may be shunted into the palmar arch without going through the fingers. The common association with other diseases presents two questions which can be only partially answered: 1. The treatment of the mild or severe anemia resulted in improvement in all. The degree of improvement varied from

slight to almost complete relief from attacks. The effects of antisiphilic treatment could not be observed in 1 patient because he did not remain under observation; in the other, who also had scleroderma and selerodactylia, complete relief from the Raynaud symptoms and great improvement in the scleroderma followed antisiphilic treatment. 2. The organic vascular disease varied from mild organic peripheral changes to severe cardiovascular disease with decompensation, and the results indicate that it and the Raynaud symptoms have a common etiology. The treatment of Raynaud's syndrome varies with the individual circumstances of each patient. In the author's 22 patients surgery of the sympathetic nervous system was a therapeutic failure but medical management gave considerable relief to a number of patients. In from twelve to thirty-five days after surgical intervention on the sympathetic nervous system the circulation returns to the preoperative level, but the cutaneous temperature remains elevated and the absence of sweating persists. This occurs in the apparent absence of the sympathetic vasoconstrictor tone. Following the so-called preganglionic sympathectomy to the upper extremity as done by White the circulatory and thermal effects were transitory; it is doubtful that they lasted longer than the traumatic effects of the operation. Vasodilatation in the fingers could be produced following recovery from surgery by local heat or median nerve block indicating the presence of nerves with vasomotor function. The importance of recognizing Raynaud's symptoms as part of some other disease cannot be overlooked. It would seem logical to direct attention to the recognition and treatment of Raynaud's symptoms as part of some other disease rather than to Raynaud's disease alone, which must be extremely rare if it exists at all.

Mucinous Carcinoma of Breast.—Saphir states that mucinous carcinoma of the breast is not a single entity but that it presents at least four definite types of tumor: 1. The true mucinous carcinoma, which consists of duct or cystic structures filled with mucinous material in which groups of, or isolated, tumor cells may still be recognizable. There are no other tumor structures present. This is apparently a rare tumor and is relatively benign. The original conception of the benignity of mucinous tumors is to be traced to this type. 2. Duct carcinoma with mucinous features, which is the most common type. Areas similar to those seen in true mucinous carcinoma are intermingled with duct carcinomatous structures. Sometimes the latter portions are seen only after sections of the whole breast have been examined. The tumors are just as malignant as simple duct carcinomas. 3. The signet ring cell mucinous carcinoma, characterized microscopically by well preserved mucin secreting cells with basophilic or clear cytoplasm and crescent shaped, compressed nuclei situated at the base of the cells. The signet ring tumor cells remain intact. Soon they become isolated from the ducts and acini, invade the stroma and may produce the most widespread metastases, particularly in the ovaries. Though duct carcinomatous structures may also be present in this variety, the metastases consist mostly of signet ring shaped cancer cells. This tumor is regarded as highly malignant. Two patients died from widespread metastases soon after the detection of the primary tumor. Yet 1 patient is alive four years after operation. 4. Intracystic papilloma with mucinous features. This is a relatively rare, nonmalignant tumor. Only 1 such tumor was observed. Grossly it consisted of a cyst measuring about 4 cm. in greatest dimension, which was filled with a hemorrhagic and mucinous material in which small, yellowish pieces of soft, granular tissue were loosely intermingled. The inner wall of the cyst presented a rather soft and friable, velvety, broadly attached tumor composed of many well circumscribed, small or minute excrescences covered and separated from one another by mucinous material. Microscopically the tumor consisted of round, oval and, more often, spindle shaped epithelial cells resembling transitional cells of the urinary tract and an insignificant, thin, connective tissue stalk. These cells were covered by a mucinous material. Because of the spindle shaped cells the tumor could be classified as a transitional type of intracystic papilloma.

Meningitis Due to Salmonella Supestifer.—Lyon and Folsom report a case of meningitis due to an unusual small motile gram-negative rod treated with sulfanilamide. Two weeks before admission the patient, a boy 2½ years of age, became suddenly ill with fever, vomiting, malaise and diarrhea. From the parents it was learned that there had been a considerable amount of raw pork in their kitchen for two or three weeks preceding the apparent onset of his illness. There is much reason to believe that the meningitis and bacilluria were caused by one of the Salmonella group, probably Salmonella supestifer (the bacillus of hog cholera) rather than Salmonella schottmülleri (bacillus paratyphoid B). Salmonella supestifer infections in man occur infrequently or else they are not recognized. The young seem to be more frequently affected, and while in them the infections are believed to be mild the most severe form is also encountered in the very young. With all the Salmonella contaminated raw pork sold and taken into homes there have been relatively few illnesses traceable to Salmonella supestifer. This can best be explained on the basis of (1) its low pathogenicity for man and (2) the failure to suspect the real causal agent. More careful bacteriologic study of the gram-negative bacilli encountered clinically would probably show a larger incidence of these infections than is generally recognized. Just what role sulfanilamide played in the management and recovery of their patient is not clear. It is possible that the patient may have recovered spontaneously. However, it is the authors' impression that the drug was directly responsible for the recovery. They also believe that relatively high blood and cerebrospinal fluid levels are required, as their patient did better clinically on high levels (from 18 to 24 mg. per hundred cubic centimeters) than on levels from 12 to 18 mg. per hundred cubic centimeters. He also did better on combined oral and intrathecal administration than on oral therapy alone. At no time was there any significant evidence of toxicity other than a grayish discoloration of the skin. The authors know of no similar instance in which a meningitis and a bacilluria caused by a motile gram-negative bacillus was treated with sulfanilamide. Cultures were taken directly from the puncture needle into nutrient broth. After from forty-eight to seventy-two hours a gram-negative bacillus possessing motility was observed. The bacilli were not agglutinated by serums which agglutinated the typhoid bacillus (Eberthella typhi), the Flexner dysentery bacillus (Eberthella paradysenteriae) the bacillus of paratyphoid A (Salmonella paratyphi) or the bacillus of paratyphoid B (Salmonella schottmülleri Sciffert). In spite of the fact that the small gram-negative bacillus did not regularly satisfy all the cultural and fermentation characteristics of Salmonella supestifer, it seemed, from purely bacteriologic grounds alone, that the organism belonged more nearly to the Salmonella group than to any other. The finding of this motile gram-negative bacillus in cerebrospinal fluid and in the urine is of particular interest. Broth cultures from the blood gave no certain evidence of a bacillemia, although they were not taken until relatively late in the clinical course and after chemotherapy was instituted.

Vitamin K in Hepatic and Biliary Diseases.—Reid studied the prothrombin deficiency and hemorrhage in 35 patients with obstructive jaundice, biliary fistula, catarrhal jaundice or cirrhosis of the liver. Definite prothrombin deficiency was found in 16 patients, and these were treated with synthetic naphthoquinone preparations; 8 received 2-methyl-1:4-naphthoquinone (menadione) in peanut oil by intramuscular injection, and 8 were given 2-methyl-1:4-naphthohydroquinone disuccinate intravenously. Prothrombin estimations were carried out for three to five days before and for seven to ten days after treatment. There were 15 patients with obstructive jaundice due to neoplasm. Their prothrombin index before operation ranged from 31 to 100 per cent, average 65 per cent. The patients were all receiving satisfactory diets; hence deficient absorption of vitamin K appears to be the main cause of a low prothrombin level in obstructive jaundice and biliary fistula. After operation much prothrombin deficiency was encountered in association with much slighter degrees of obstructive jaundice. In 7 a pronounced prothrombin deficiency developed from the second to the sixth day, the prothrombin index being reduced from 5 to 25 per cent in the first twenty-four hours and from 20 to 50 per cent between the second and the sixth day. These 7 patients responded immediately to treatment with naphthoquinone and the prothrombin index rapidly returned to normal; hence liver damage, while it may be a contributory factor, does not play an important part in postoperative deficiency. It appears that a deficient intake of vitamin K (green vegetables were not taken for at least a week after operation) may be important in causing the pronounced postoperative fall in the prothrombin index. Of the 8 patients with nonmalignant obstructive jaundice, all were slightly jaundiced. Before operation the prothrombin index was never below 75 per cent; 6 were operated on. In 4 the prothrombin index ranged between 75 and 80 per cent in the first two postoperative days; thereafter normal values were found. In another patient it fell to 57 per cent on the fourth day and in the sixth patient it fell to 25 per cent after one week, when hemorrhage from the wound was observed. The prothrombin index of the 6 patients with catarrhal jaundice was never below 90 per cent and the plasma

bilirubin was 5 and 10 mg. per hundred cubic centimeters respectively in the 2 patients with the mild form of the disease. In the 3 patients with moderate attacks the lowest prothrombin indexes were 80, 72 and 65 per cent and the plasma bilirubin was 18, 9 and 7 mg., respectively. The prothrombin index was 20 per cent and the plasma bilirubin 35 mg. at the height of the disease in the patient with severe clinical manifestations. The amount of prothrombin in the 4 patients with cirrhosis of the liver was always moderately reduced; the index ranged from 65 to 80 per cent. On an ordinary mixed diet the level fluctuated between these figures. Normal values were never reached, and there was practically no response to synthetic vitamin K. From a study of the 3 patients with obstructive jaundice followed by postoperative hemorrhage the author concludes that prothrombin deficiency is not, even when severe, always associated with hemorrhage. It is considered responsible only for prolonging hemorrhage after it has been caused by other factors, especially injury. The water soluble preparation 2-methyl-1:4-naphthohydroquinone disuccinate, injected intravenously, has been found as efficient as menadione in increasing blood prothrombin. The action of the first preparation appears to be more rapid though less sustained than the latter. Its disadvantage is that it is not stable and must be dissolved in water immediately before use. A close analogy between hemorrhage in jaundice and hemophilia is made. In both an upset in the coagulation mechanism exists, in the one it is due to prothrombin deficiency and in the other to an unknown congenital defect.

Reactions After Ultraviolet Irradiation.—Eidinow studied local reactions and specific immunity response when a standard quantity of antigen (hay pollen toxin or T. A. B. vaccine) was injected intradermally into areas of normal skin of 14 patients and their skin was irradiated with ultraviolet rays. He observed that exposure of the skin to ultraviolet radiation diminishes the local reaction normally produced in allergic patients by scarification and the application of hay pollen toxin. Intradermal injections of hay pollen toxin into an area of irradiated and erythematous skin of allergic patients excites violent symptoms and signs of hay fever or asthma with collapse. Intradermal injections of T. A. B. vaccine into areas of skin rendered erythematous by ultraviolet rays will provoke an agglutinin (H and O groups) titer in the blood serum more than ten times as great as a similar intradermal injection into areas of normal skin. The erythema reaction following exposure of the skin to ultraviolet rays may thus be used to increase local and general immunity.

Sciatica.—Kellgren describes a clinical examination which facilitates diagnosis of sciatica. The first point to consider is the distribution of the deep pain and tenderness. The patient is asked to map out roughly the distribution of his deep pain and tenderness. From this information the segmental innervation of

the source of pain, whether superficial or deep, can be determined. The movements of the knee, hip, sacroiliac joints and lumbosacral spine are examined. The appropriate region is carefully palpated for a painful structure, and after it has been defined it is explored with a needle point, when the full spontaneous pain should be reproduced. The painful structure is infiltrated with 2 per cent procaine hydrochloride and in favorable cases the symptoms and signs may be completely abolished; more usually they are only much relieved, as it is rarely possible to anesthetize deep-lying structures. Deep-seated painful structures, such as an interspinous ligament or ligamentum flavum, can be reached with the exploring needle. In the few patients with pain in the lumbosacral spine in which the exploring needle fails to reveal any painful structure it is probable that the source of pain lies inside the spinal canal, and displacement of an intervertebral disk is to be suspected. In cases in which there are clear signs of an intraspinal source of pain but no evidence of nerve involvement, the source of pain is probably the posterior common ligament. More often there is some evidence of pressure on a nerve root; thus an area of cutaneous pain may be added to the area of deep pain. The earliest signs of nerve pressure will be periods of numbness, recovering with tingling but without detectable sensory loss. The next stage consists of hyperalgesia combined with loss of light touch, then loss of all sensation except delayed pain and finally complete sensory loss. These sensory changes are distributed over the dermatome corresponding to the root or roots pressed on, and they form the most reliable evidence of nerve involvement. Muscular paralysis is of value only when it is severe. The ankle jerk is of more value, but it may be absent in cases of simple referred pain distributed over the first sacral segment. Of the author's 70 patients, 50 suffered from ligamentous and muscular lesions; in only 22 of these was any change in the underlying bones and joints revealed in roentgenograms. Of 15 patients with displacement of an intervertebral disk, 13 showed evidence of root pressure and in 2 the pain resulted from a disturbance of the posterior common ligament. The pain of the remaining 5 with nerve involvement resulted from miscellaneous nervous diseases. In no case could the symptoms and signs be ascribed to an interstitial neuritis of the sciatic nerve.

Diphtheria Antitoxic Serums.—According to Kekwick and his associates, examination of diphtheria antitoxic horse serums by electrophoretic analysis has shown that of the three separable globulin components, two, the β (beta) and γ (gamma) fractions, have antitoxic activity. Both these proteins are specific antibodies to the classic diphtheria toxin, prepared with a Park-Williams 8 strain, in that they neutralize this toxin in the usual animal test for potency ($L+$) and flocculate with the toxin in a balanced mixture (Lf). There are striking differences between the two antitoxins as shown by the flocculation times, the *in vivo/in vitro* ($L+ / Lf$) ratios and the empiric composition of the floccules. The relative and absolute amounts of the β and γ antitoxins altered during the course of immunization in horses. Initially the amount of γ antitoxin increased more rapidly than the β antitoxin but soon reached a steady value. The β antitoxin of the serum increased more slowly to a much higher maximal value and contributed the major portion of the total unitage obtained at the end of the course of immunization. There may be a correlation between the avidity of a serum and the relative proportion of γ antitoxin present. The γ globulin (containing the γ antitoxin) is precipitated at lower salt concentrations than the β globulin and thus tends to be precipitated in the "euglobulin" fraction in the classic salting-out method of serum concentration. The γ antitoxin appears in large measure to be lost in the "pepsin process" of serum concentration, the product there being probably a modified β globulin. Early bleedings during a course of immunization, late bleedings, salt-concentrated antitoxin (pseudoglobulin) and pepsin-treated antitoxin show, in this order, a progressive decrease in the proportion of the total unitage which is contributed by the γ antitoxin. It is possible that the relative and absolute amounts of the two antibodies in any given sample of serum may have a bearing on its therapeutic efficiency.

Recent Advances in Use of Acridine Antiseptics. A. Albert.—p. 482.

Poliomyelitis.—Helms and Willecocks discuss certain epidemiologic features of the 1937-1938 epidemic of acute anterior poliomyelitis in New South Wales. During the first nine months of 1937 the average monthly incidence was 2 cases. Between October 3 and October 30 5 cases occurred in the metropolitan area and 7 in rural districts. Up to Sept. 30, 1938 there were a total of 711 cases. The epidemic reached its peak earlier in the metropolitan area than in the rest of New South Wales. A study of the meteorologic elements from October 1937 to September 1938 suggest that the temperature and absolute humidity curves exhibit the closest correlation with the increase and decrease in the number of cases. The latter, commencing in spring, attains a maximum in a midsummer month and then declines. A somewhat similar correlation was suggested in the incidence of seasonal rainfall in northern parts of New South Wales. In the metropolitan area, during the early weeks of the epidemic and while the weekly incidence was increasing, severe paralysis developed in a greater proportion of patients than during the later stages of the epidemic. In rural districts the tendency may be masked by the fact that a relatively small population is spread over a large area. The number of deaths was greater in the rural districts at the beginning and at the height of the epidemic than in the later stages. In the metropolitan area there appears to be a tendency for the age group up to 4 years to be proportionately larger and the group more than 15 years of age to be proportionately smaller at the beginning of the epidemic than in its later stages. This tendency may be masked in rural districts for the same reason that the severity of paralysis was masked. The fatality rate in New South Wales was 2.5 per cent, or 17 deaths. For the rural districts it was 4.08 per cent, or 11 deaths. The oldest patient was 63 years and the youngest 7 months of age; 64 per cent of 601 patients were males and 34 per cent females. There were only 5 patients less than 12 months of age. The percentage of patients less than 10 years of age was greater in the metropolitan area (paralytic cases 76.8 per cent) than in rural districts (paralytic cases 53.5 per cent). In the 1937-1938 epidemic of poliomyelitis in New South Wales 5 patients contracted the disease during pregnancy, 1 in the fifth, 2 in the sixth, 1 in the eighth and 1 in the ninth month of gestation. In a study of these instances and 13 others reported in the literature there is only 1 in which spontaneous abortion followed closely on the infection. In 13 of the 15 patients whose pregnancy continued beyond the seventh month, the delivery and the child were normal. In the other 2 cesarean section was performed because of respiratory paralysis. Poliomyelitis in pregnancy uncomplicated by respiratory paralysis is not an indication for the interruption of the pregnancy. In the presence of respiratory paralysis during the last weeks of pregnancy, respiration may be facilitated by the removal of the fetus. Of the 711 patients 7 were known to have had a tonsillectomy and adenoidectomy from seven to twenty-two days prior to the onset of the illness. Bulbar and spinal paralysis developed in 3 of these 7 patients, 2 had paralysis of the palate, 1 had spinal paralysis with no evidence of bulbar involvement and 1 patient had the nonparalytic form of the disease. There were no deaths. A review of the literature supports the contention that operations on the throat and nose favor the development of poliomyelitis of the bulbar type. When this disease is prevalent, the risk of subsequent invasion by the virus should be well weighed before tonsillectomies or adenoidectomies are undertaken.

*Influence of Gas Mask Breathing on Human Circulation. H. Hofer.—p. 331.

Complete Disappearance of Radical Pulse During Attack of Angina Pectoris (with Remarks on Coronary Theory of Angina Pectoris). F. Mainzer.—p. 361.

Gas Mask Breathing and Circulation.—The development of angina pectoris in a man aged 51 following a gas mask drill, induced Hofer to study the influence of gas mask breathing on the circulation. Investigations were made on 50 persons of both sexes, ranging in age from 16 to 55 years. Electrocardiograms were made during rest and after measured exertion, together with tests of the circulatory regulation according to the Schellong method, which in addition to a systematic control of the pulse and blood pressure measures and evaluates the QRS complex. All tests were made first without and then with the use of the gas mask. The putting on of the gas mask, even with the patient at rest, caused deeper and slower breathing; after the work test all persons manifested dyspnea and profuse perspiration. The pulse was usually somewhat accelerated by breathing through the mask when the person was at rest; during the work test, however, it was somewhat retarded. Systolic and diastolic pressures usually increased when breathing was through the mask by several millimeters, both at rest and during the work test. The electrocardiogram, while breathing was through a mask, revealed slight changes in all parts of the curve, but they were not pronounced or significant and differed only slightly from the usual electrocardiographic changes caused by work tests. It appeared that breathing through a gas mask does not cause a characteristic circulatory effect. At any rate there were no electrocardiographic changes which would indicate unequivocally an anoxemia or coronary insufficiency. The author concludes that gas mask breathing is well tolerated by healthy persons, but that impairment is possible in patients with circulatory disorders and in those threatened by such disorders.

*Estrogen in Gonococcal Vulvovaginitis in Little Girls. A. V. Ferrari.—p. 142.

Estrogen in Gonococcal Vulvovaginitis in Girls.—According to Ferrari, vulvovaginitis in little girls is rare in families practicing hygiene and frequent in families which do not. He observed 147 patients ranging in age from 3 to 10. The condition was complicated by urethritis in 84 and by cervicitis in 60. The internal genitalia were not involved. For therapeutic purposes the author divided the patients in three groups. The first group consisted of 24 patients who presented no urethral or cervical infection. They were given estrogen as the sole treatment. The substance was administered intramuscularly in doses of 10,000 international units (dehydrofolliculin benzoate international units) at five day intervals until ten to twenty injections had been given. The second and third groups consisted of 48 and 75 patients respectively, with and without urethral and cervical complications. Patients in the second group were treated by irrigations of the external genitalia and vagina with a weak solution of potassium permanganate or of vaginal and urethral irrigations with a 2 per cent solution of strong protein silver or silver nitrate, after which a glycerin suppository containing 2 per cent of strong protein silver was inserted into the vagina. They were kept in bed for one hour. The treatment was administered twice daily until the infection was controlled and once daily for a month thereafter. Patients in the third group received estrogen in the same amount as those in the first group and local treatment as given to the second group. Vaccines, proteinotherapy and chemotherapy were not resorted to. Gonococci disappeared from the secretions within thirty days in 18 of the 24 patients who had estrogen alone and in 60 of 75 who were given estrogen and local treatment. Gonococci disappeared from the secretions within forty days in 34 of 48 patients who had local

treatment alone. Recurrence took place within six months in 10 of 18 patients of the estrogen group, in 29 of 60 in the combined group and in 15 of 34 of the local treatment group. Cure has been permanent up to the present, four years after discontinuation of the treatment, in 8 of 24 patients who had estrogen alone, in 31 of 75 who had the combined estrogen and local treatment, and in 19 of 48 who had the local treatment alone. Patients with recurrences and failures had two months of rest without any treatment, after which they were given vaccines, proteins or sulfanilamide. Of a large number of patients who had estrogen alone or combined with local treatment the general health improved, the patients gained weight and long standing eczema was controlled. Sixteen patients complained of painful swelling of breasts and 20 of moderate menstrual loss of blood. The symptoms disappeared in the majority of cases on discontinuation of the treatment. One girl, aged 10, presented signs of puberty and began to menstruate as the result of treatment. The author concludes that estrogen treatment is indicated only in exceptional cases of gonorrheal vulvovaginitis recently acquired and in cases without urethral and cervical involvement which are not controlled by the usual treatment.

*Sulfanilamide Resistance in Gonorrhea. E. Bizzozero.—p. 93.

Action of Ascorbic Acid on Glycemia of Patients with Liver Diseases. A. Turchetti and G. Schirosa.—p. 96.

Sulfanilamide Resistance in Gonorrhea.—According to Bizzozero, primary or secondary resistance of the gonococcus to sulfanilamide depends on the habituation of the bacteria to the drug when the latter is administered in small doses or at irregular intervals. Seventeen patients with early untreated gonorrhea were given progressively increasing doses of 0.5 to 3 Gm. for ten or fifteen days until a total of 16 or 18 Gm. was reached. This was followed by a four or five day period of rest, after which diminishing doses of 3 to 1 Gm. of the drug were administered up to a total of 12 to 20 Gm. in six to ten days. Resistance to the drug developed in 13 cases in ten to fifteen days. In another group, 30 patients were given 0.5 Gm. of sulfanilamide for three days. Local inflammation and pain abated in all of these. The urine of 16 patients became clear. It contained a few filaments with scanty pus cells. Gonococci disappeared from the filaments in 6 cases. The number of gonococci in the filaments did not change in 10 cases. The author concludes that the bactericidal properties of the drug are impaired if resistance is established. Administration of small early doses of the drug may result in the establishment of resistance. It is therefore advisable to give large doses of the drug from the beginning of the treatment. It would be preferable to interrupt treatment of the few patients who prove to be intolerant to the drug rather than to risk establishing resistance.

*Epinephrine in Acute and Chronic Diseases of Brain. F. Serraino.—p. 289.

*Rapid Desensitization with Calcium Before Reinjection of Antitetanus Serum. L. Faraglia.—p. 305.

Epinephrine in Diseases of Brain.—Serraino resorted to intravenous injections of epinephrine in 30 cases of essential or postencephalitic parkinsonism, in 4 of genuine epilepsy, in 3 of acute encephalitis and in 5 of rheumatic chorea. Patients with parkinsonism were given a daily dose of 0.1 or 0.2 mg. of epinephrine for ten days. The treatment was discontinued for from three to five days and then repeated. Children with rheumatic chorea and acute encephalitis were given small doses for from four to eight days and in a few cases a daily dose of 0.1 mg. for the last two days of treatment. The latter was well tolerated. Tremor and tics of patients with parkinsonism improved, whereas hypertonia, oculogyric crises, trophic and secretory disorders were not influenced. Epileptic seizures reappeared five months after discontinuation of the treatment. The convulsions became sporadic after administration of a second series of treatments. Chorea and symptoms of encephalitis

regressed to a complete cure after a number of injections which varied from four to ten. The author believes that epinephrine causes dilatation of the cerebral vessels with consequent improvement of the metabolism of the nervous tissues.

Desensitization with Calcium.—Faraglia injected calcium intravenously in an attempt to prevent anaphylactic reaction from a second or third injection of antitetanus serum. A solution of 0.5 Gm. of calcium gluconate and 0.05 Gm. of calcium lactate in 5 cc. of doubly distilled water was injected fifteen minutes before the intramuscular injection of antitetanus serum in 12 patients who had had antitetanus serum administered to them one or more years previously. Patients who manifested anaphylactic reactions on the first or second injection of the serum were given two intravenous injections of 5 cc. of the calcium solution. None of the 12 patients manifested signs or symptoms of anaphylactic shock. The author concludes that desensitization may be rapidly and safely obtained by intravenous administration of calcium.

Clinical Significance of Complement Fixation Reaction in Tuberculosis. N. Kusunoki.—p. 656.

*Sepsis Tuberculosis Acutissima. C. Velten and Edith Fatum.—p. 672.

Primary and Progressive Pulmonary Tuberculosis.

Opinions regarding the relationship between primary tuberculous infection and progressive pulmonary tuberculosis are contradictory, and this contradiction is largely due to lack of uniform interpretations and nomenclature. Ljung continued investigations on nurses begun by Kristenson. The group consisted originally of 124 students of the school for nurses at the university hospital in Uppsala. During their three years of training Kristenson repeatedly subjected them to roentgenologic examination. All student nurses were examined at the beginning of their training clinically and roentgenologically. The Pirquet tuberculin test was made and read after forty-eight hours and repeated on nurses whose reaction was negative. Thirty-one student nurses who gave negative reactions to the second test were designated as negative; 23 of these became positive in less than a year, while after two years only 2 remained negative. These 2 were vaccinated with BCG and were disregarded in the subsequent investigation. The remaining 29 nurses with negative Pirquet reactions at the beginning of their training and the 93 who had been Pirquet positive from the beginning were reexamined about ten years later. This follow-up suggested that primary tuberculosis is generally not more dangerous in adults than it is in school children but that a progressive, destructive, postprimary pulmonary tuberculosis may develop already during the first year after the primary infection. There are as yet no data to prove with certainty that progressive pulmonary tuberculosis develops more frequently in those who had their primary infection after attaining adulthood than in those who had their primary infection in childhood. To clarify this question it would be necessary to make repeated tuberculin tests on the entire population. The majority of investigations on nursing personnel indicates that those who in the beginning have negative tuberculin reactions are in greater danger of contracting destructive tuberculosis than are those with positive tuberculin reactions. The destructive reinfection tuberculosis appears especially during the first two years after the manifest or latent primary tuberculosis. Experiences with the nursing personnel cannot be applied to the average population. Whether phthisis will develop in a tuberculous person seems to depend not so much on when the primary infection has taken place but rather on the frequency of incidence of tuberculous infection and especially on the congenital and acquired nonspecific resistance of the person.

Sepsis Tuberculosis Acutissima.—According to Velten and Fatum sepsis tuberculosis acutissima is infrequent. Landouzy was the first to call attention to this form as an independent

disease entity. He differentiated three types of acute tuberculosis, namely caseous pneumonia, miliary tuberculosis and typhobacillosis. The last named form pursues a sepsis-like course following acute tuberculous dissemination. The septic manifestations justify its being identified as an independent disease entity. It is characterized by intermittent fever which becomes continuous; by a variable pulse, either accelerated or retarded; by swelling of the liver and spleen, and by gastrointestinal disturbances. In contradistinction to miliary tuberculosis there is no cyanosis, dyspnea or roseola. Characteristic blood changes are absent, but in many cases tubercle bacilli are demonstrable in the blood. This form of acute tuberculosis has been discussed under such terms as "tuberculous sepsis," "sepsis tuberculosis gravissima," "sepsis tuberculosis acutissima" or "aractive generalized tuberculosis." The clinical diagnosis is difficult and possible only if tuberculous bacillæmia exists in the presence of Landouzy's syndrome. Some consider correct diagnosis possible only on the basis of microscopic studies done at necropsy. Microscopic studies reveal not inflammatory tissues, as in other forms of tuberculosis, but rather necroses with pyknotic nuclei and nuclear debris not sharply defined against the surrounding tissue. All observers found numerous tubercle bacilli in the necrotic foci. The surrounding tissue is usually free from tubercle bacilli or, at most, contains some bacilli in the vascular walls and the lymph channels. The appearance of extensive necroses without the slightest reaction in the surrounding tissue demonstrates definitely the lack of reactive capacity of the organism. The organism is in a state of negative anergy. Its defensive powers have been depleted and there is an unrestricted dissemination. The state of anergy manifests itself in the negative outcome of the tuberculin reaction. Sepsis tuberculosis acutissima frequently concurs with diseases of the hemopoietic system, such as leukemia, polycythemia, pernicious anemia, panmyelophthisis and acute agranulocytosis. Certain similarities in the clinical course led some investigators to believe that tuberculosis of the hilus lymph nodes is also a form of sepsis tuberculosis acutissima, and some authors admit that these lesions presuppose a similar biologic reaction and that they often present similar clinical aspects. Wyss stated that tuberculosis of the bronchial lymph nodes in children is identical with sepsis tuberculosis acutissima. The authors think that these forms differ in that the tuberculous process by its manifestation in the hilus lymph nodes has already followed a definite pathway, whereas sepsis tuberculosis acutissima represents that undifferentiated state of reaction in which all variations are still possible. They conclude that sepsis tuberculosis acutissima is characterized by the absence of a specific allergy. It is probable that constitutional factors and infection at an advanced age in the presence of temporary deficient resistance play a part in the pathogenesis.

Sterility During Injections with Special Consideration of Prophylaxis of Gas Gangrene. A. Hübner.—p. 725.

*Arteriotomy in Endangiitis Obliterans. H. Schaer.—p. 730.

Excision of Wounds. W. Noetzel.—p. 739.

Arteriotomy in Endangiitis Obliterans.—Periarterial sympathectomy for the treatment of endangiitis obliterans, introduced by Leriche in 1914, survived, according to Schaer, for a long time in spite of failures and of the anatomic demonstration that not all sympathetic nerve fibers are destroyed in this procedure. It is now generally conceded that the success of a periarterial sympathectomy is only temporary. Leriche himself discarded the method in favor of arteriotomy. Lumbar and cervical sympathectomies were practiced with technical modifications by a number of investigators after 1925. In recent years the opinion has gained ground that ganglionectomy is preferable to division of the rami communicantes. Arteriotomy, introduced by Leriche in 1916, has found more adherents in recent years. Leriche maintains that a thrombosed artery is the starting point of many vasoconstrictive reflexes which prevent formation of a collateral circulation and that for this reason every localized arterial thrombosis should be removed by a resection extending in each direction beyond the obliteration. This procedure resulted

in 38 per cent of cures of cases of Buerger's disease and in 43 per cent of cases of arteriosclerotic obliteration. The author employed this method in 4 cases. The treatment resulted in a failure in 1 case, while in another case the improvement was only temporary. In the other 2 cases the treatment proved highly successful and the results permanent. The author stresses that after all conservative measures have been exhausted an arteriogram should be made to determine the local extension of the process. The thrombosed artery should be removed as completely as possible. If the thrombosis is too extensive to permit surgical removal of all the diseased vessel, ganglionectomy or resection of the sympathetic trunk is advisable.

*Does Inhalation of Horse Dust Containing Cutaneous Scales Produce Allergy Against Horse Serum? W. Sprügel.—p. 559.

Inhalation of Cutaneous Scales from Horses and Allergy to Horse Serum.—Reports to the effect that inhalation of cutaneous scales of horses can produce hypersensitivity to horse serum induced Sprügel to investigate the subject in soldiers who come in contact with horses. He made tests on two groups of 50 soldiers each. One group was in constant contact with horses, whereas the other was composed of men who had never been in contact with horses. Previous serum injections or consumption of horse meat was ruled out. Intracutaneous wheals were produced with 0.05 cc. of horse serum diluted 1:10 with physiologic solution of sodium chloride. Of the 50 men who handled horses, 19 showed after from ten to thirty minutes local redness and mild swelling up to the size of a quarter (24 mm.) about the site of injection. Only two men showed more severe reactions, somewhat like urticarial wheals, the areas varying in size from a silver dollar (38 mm.) to the palm of a small hand. The other 29 men who handled horses had negative reactions. Of the group of men who had never been in contact with horses, 21 reacted with local redness and mild swelling, one man reacted by developing a wheal. The other 28 had a negative reaction. The high percentage of "positive" reactors is without significance because, as H. Schmidt has pointed out, a specific reaction is characterized by the development of a wide urticarial ring with occasional pseudopodia-like projections into the surrounding area of erythema. Simple redness and mild swelling are pseudoreactions of a nonspecific nature. The almost identical percentages in the two groups indicate the unlikelihood of inhalation of horse scales producing an allergy against horse serum. The antigen of the cutaneous scales which elicits attacks in asthma patients sensitive to horses is presumably not the same antigen as the protein of horse serum.

*Experimental Studies on Treatment of Malaria: I. Combination Treatment of Malaria in Canaries with Quinine and Sulfonamide. M. Terasak, T. Sugimoto and N. Kinosita.—p. 180.

Sulfonamide Derivatives and Quinine in Malaria.—Terasak and his associates endeavored to ascertain the synergistic action of sulfonamide derivatives in combination with quinine in the treatment of malaria in canaries. It is known that the sulfonamide series of drugs alone are ineffective in curing this parasitic disease, but this investigation shows that when used as a supplement to quinine they exert an appreciable therapeutic effect. The first part of the report deals with the authors' attempt to determine the toxic and lethal doses of various sulfonamide drugs on canaries. The five different compounds tested in this respect show a marked difference, azosulfamide being the least toxic (the lethal dose 75 mg. to 10 Gm. of body weight) and both sulfanilamide and sulfapyridine the

most toxic (the lethal dose 15 mg. to 10 Gm. of body weight). When compared with the lethal dose for mice, the relative toxicity of these preparations was approximately identical. For the second stage of their investigation the authors transmitted the disease to canaries by intramuscular injection of 0.2 cc. of about 10 per cent suspension of infected blood in physiologic solution of sodium chloride. The sulfonamide derivatives were injected on the ventral aspect of the bird, while quinine was administered on the dorsal aspect, the injections having been continued once daily for five days in each bird. From a small series of experiments the authors were able to prove that when given alone the sulfonamide derivatives exerted no therapeutic effect, the bird dying in about two weeks as in the case of untreated controls. The administration of quinine hydrochloride alone, on the other hand, led to the cure of the disease in the bird but required four weeks of therapy; but quinine in combination with sulfonamide derivatives so effectively hastened recovery that in some instances the number of parasites in the peripheral blood was never high, while in the remaining cases the course of the disease was shortened by at least one week. Further investigations along this line are in progress.

*Experimental Studies on Skin Absorption of Testicular Hormone. N. Sato.—p. 187.

Cutaneous Absorption of Androgen.—The substance used by Sato in his experimental observations was prepared from the whole male organs of mammals by a pharmaceutical concern and, although it was not a pure chemical substance, contained a potent androgenic principle. The test animals (*Mus norvegicus* var. *albus*) were anesthetized with ether and the testes were completely removed, care being taken to avoid undue traumatization of the epididymis. The experimental procedures were begun on the fourth day after the operation, one group of animals receiving daily subcutaneous injections of 0.2 cc. of the substance, the second treated with inunctions of 0.2 cc. over a shaved skin area approximately 6 sq. cm. twice or thrice daily, and the third group left untreated as controls. After twenty-five days of treatment the animals were killed and the tissues around the sex organs carefully removed and immediately fixed in solution of formaldehyde U. S. P. diluted 1:10, in which they were dehydrated for twenty-four hours. Each component part of the sex organ (penis, prostate, seminal vesicle, epididymis, seminiferous tubule) from each animal was then dissected out and weighed on a torsion balance. The results of determination showed that, on the basis of the weight of each organ of the control group as 1, the organs of the androgen treated animals increased in weight from 1.3 to 1.7. The animals receiving the substance by injection exhibited a slightly greater gain in weight of the sex organs than those of animals treated by inunction. The preparation used in these experiments being lipid soluble, the author tinted the substance with sudan III, and the microscopic sections of the androgen-anointed skin revealed the concentration of the dye at the root of the hair follicles and the accumulation in the sebaceous glands of the skin. From these observations the author concluded that either by the injection or by the inunction of androgen on the skin of castrated animals the atrophy of the sex organs could be prevented and that the substance was absorbed through the sebaceous glands of the skin.

Complaints of Cardiac Patients. M. V. Burgsdorf.—p. 657.

Closed Plaster Method of Treatment of Gunshot Fractures.—Extensive experience with the closed plaster of paris method of treatment of gunshot fractures in the orthopedic clinic of Professor Turner in Leningrad has demonstrated, according

to Novotel'nov, its superiority over the older methods. Certain physiologic principles, however, must be adhered to, namely application of the cast with the limb in physiologic position; that is, with the two adjacent joints slightly flexed. The function of the cast is to immobilize the fragments and the extremity, including the two adjacent joints. Wounds were treated by careful débridement, covered with dry gauze (never cotton) and encased in circular plaster of paris bandages. Primary suturing of wounds was not practiced. Badly infected wounds were covered, after wide excision, with gauze saturated in physiologic solution of sodium chloride or hypertonic saline solution and circular plaster of paris bandages were applied. The wounds were not redressed for periods of from ten to forty days. When a rise in temperature, leukocytosis, the sedimentation test and the patient's general condition necessitated a change of dressing, a window was cut in the cast, dressings were changed and the window closed by fresh plaster of paris circular bandages. Saturation of the cast with discharges from the wound and the offensive odor do not constitute per se an indication for removal of the cast. The closed plaster method has been adopted as standard procedure in Professor Turner's clinic for gunshot fractures of the shoulder, arm, elbow, wrist, knee, leg and foot. In fractures of the femur, the method is used only when there is no shortness of the leg or when the difference in length of the two legs does not exceed 2 cm. Limbs with more extensive shortening are treated by traction in a Böhler's splint. As soon as consolidation is evident (on an average of thirty days) the traction is discontinued and the circular plaster cast is applied. Septic wounds and wounds infected with anaerobes were treated by hypertonic salt solution. The author relies in combating infection principally on physical rather than on chemical antiseptics. This consists of efficient drainage of the wound, of keeping the wound at rest by fewer dressings and of placing the entire limb at rest. A comparison of the results obtained with the closed method and with the method in which a window was cut out to allow frequent dressings demonstrated that better results were accomplished both for the fresh and for the already infected wounds with the closed method. The favorable effect of the closed plaster method is probably due in part to conservation of moisture and heat, elements essential in regeneration of tissue. Mortality with this method for a period of four months amounted to 0.4 per cent. There was not a single amputation. Septic patients were given sulfanilamide in a solution of dextrose intravenously and vitamin C. For severe neuralgic pain and for the phantom pain after amputation, vitamin B₁ in physiologic solution of sodium chloride was given in daily doses of 5 mg. intravenously, intramuscularly or subcutaneously. In the last two months, the author's clinic has adopted the use of prepared specific polyvalent pyogenic bacteriophage. The bacterial flora of the wound contained not infrequently *Bacillus perfringens* and other anaerobes, but there was no instance of anaerobic infection. Apparently anaerobes develop only in tissues previously damaged by the action of pyogenic micro-organisms, in particular by the *Streptococcus*. While the number of patients treated with bacteriophage is too small to form a definite conclusion, the author is under the impression that the combination of the two methods, closed plaster method and the application of bacteriophage, improves the results of the closed plaster method alone.

*Diagnosis of Cancer of Lungs with Special Regard to Possibilities of Early Diagnosis. N. Christiansen.—p. 327.
*Xanthomatosis in Vascular System. J. Hoffmeyer.—p. 365.

Early Diagnosis of Cancer of Lungs.—Christiansen says that in order to arrive at the earliest possible diagnosis of pulmonary cancer there must be collaboration between the general practitioner, to find cases with a suggestive history, the diagnostic clinic, to single out the objectively suspected cases, and the thoracic surgeon, to decide whether a tumor of the lung

is present and whether it is operable. He stresses the essential cooperation of the practitioner, who must constantly have in mind the diagnosis of a pulmonary tumor; his task is difficult, since primary malignant pulmonary tumors are still infrequent in the general practice and the initial symptoms are often atypical. The symptoms of cancer of the lung are irritation, occlusion, ulceration, infection, invasion, compression, toxemia and metastases. The peripheral, so-called parenchymatous, tumors may develop for a long time without pulmonary symptoms and may first be manifested by their toxic effects, eventually in combination with symptoms of compression. Only cases presenting symptoms in the first four categories may be considered operable, and none of these symptoms can be said to be pathognomonic for cancer. The author suggests that all patients over 35 years of age with pulmonary symptoms of uncertain etiology, especially when tuberculosis cannot be established, who do not improve after medical treatment of from four to five weeks should be suspected and examined more closely; patients with hemoptysis, pain in the thorax and dyspnea, when another cause cannot quickly be established, should be examined without delay and those with a general toxic condition should also be suspected, even though pulmonary symptoms are absent. Of his 28 cases of histologically verified malignant tumor of the lung only 6 were in an early stage and only 2 of these had been recognized on the first examination. He concludes that while the chances of detecting a lung cancer while it is still operable are slight, the interest of the physician in early diagnosis has been awakened and one may, thanks to modern surgery, look to the future with some optimism.

Xanthomatosis in Vascular System.—Hoffmeyer describes in detail a case of essential general xanthomatosis in a woman aged 46 with a history of xanthomatous nodules localized symmetrically in the tendons and fasciae of both upper and lower extremities for many years, rapid development of a typical clinical angina pectoris during a year and a half and death with symptoms of coronary thrombosis. There were pronounced xanthomatous changes in the endocardium, aorta, coronary arteries, carotid and basal arteries of the brain, together with significant lipid deposits in the small arteries and the arterioli and pathologic fat deposits in the liver, kidneys, adrenals and thyroid gland. The author asserts that the pathologic anatomy of vascular xanthomatosis greatly resembles that of arteriosclerosis, the differences observed being quantitative, and suggests that arteriosclerosis may develop on the basis of a far weaker and less acute disturbance of the cholesterol metabolism than that in vascular xanthomatosis. While the etiology of essential xanthomatosis is uncertain, a hereditary factor, he says, undoubtedly plays a part.

9:481-550 (Feb. 15) 1941

*Eye Symptoms in Malignant Tumors of Rhinopharynx. E. Godtfredsen.—p. 493.

Eye Symptoms in Malignant Tumors of Rhinopharynx.—Godtfredsen stresses the vague and uncharacteristic early symptoms in malignant tumors of the rhinopharynx. In not a few cases the general condition is surprisingly good. Metastases to the lymph nodes occur early, with typical localization below the mastoid process and behind the mandibular angle. The close relation of the tumor to the base of the brain and its tendency to invade cause lesions of the cranial nerves, especially the nerves of the eye. Of the 64 malignant tumors of the rhinopharynx in patients aged from 16 to 76 treated at the Copenhagen Radium Station from 1931 to 1940, 20, or 30 per cent, showed eye symptoms, most often paralysis of the abducens (17 cases), least often lesion of the optic nerve (4 cases). In all, fifty lesions of the nerves of the eye were established in the 20 patients. The author says that, while the prognosis in these tumors is grave, roentgen therapy according to Coutard's principle can, if instituted in time, lead to recovery. Of the 20 patients, 7 were alive and without symptoms after an observation period of from six months to seven and one-fourth years.

Book Notices

Chemical Warfare. By Curt Wachtel, Founder Pharmacological Section of the Kaiser Wilhelm Institute. Cloth. Price, \$4. Pp. 312. Brooklyn: Chemical Publishing Co., Inc., 1941.

This is essentially a primer of chemical warfare, intended to be "comprehensible not only to chemists, physicians, engineers and military experts, but also to the laymen who are the prospective individual victims of the war gases." Consequently it is not to be compared with the standard works on the subject as a source of technical information. It was obviously hastily put together and was edited poorly or not at all. In spite of its numerous defects it makes interesting reading, largely because it is written in narrative style, because it records the personal experiences of the author, who played an active part in chemical warfare in the first World War, and because it summarizes a large amount of information concerning individual chemical agents. The name of Fritz Haber, originator and director of the Chemical Section of the German War Department and also originator of the process used for fixing atmospheric nitrogen, is prominent in the book. The volume may be read with profit by those who wish a general, rather than a technical, treatment of the subject of chemical warfare, including its economic as well as its chemical and military aspects.

Surgery of Modern Warfare. By Sixty-Five Contributors. Edited by Hamilton Bailey, F.R.C.S., Surgeon, Royal Northern Hospital, London. In Two Volumes. Volume I. Cloth. Price, \$10. Pp. 480, with 502 illustrations. Baltimore: William Wood & Company, 1941.

The editor of this work is well known to surgeons of the Western Hemisphere through his writings and his textbook on *Physical Signs in Clinical Surgery*. In this volume are demonstrated anew the qualities that made his textbook so popular, the free, almost extravagant use of illustrations to amplify and adorn the clear and concisely written matter of the book. After reading the names of the contributors one must agree with the editor's statement that "This is a work written by a team which can claim to represent British surgery." The contributions come from surgeons in all arms of the services and from all parts of Great Britain.

This volume is divided into eight sections, each one comprising a varying number of chapters. Sections 1 and 2 cover wounds in their general and special considerations. The next three sections deal with wounds of the trunk, blood vessels, peripheral nerves and tendons. Section 6 gives methods of immobilizing the limbs, section 7 covers wounds of the hand and foot, while section 8 begins the consideration of wounds of the bones and joints. With such a large number of contributors, one might expect an appreciable variation in interest and presentation in the many chapters, each by a different author; but while there is inevitably a slight overlap of subject matter, it does not make for annoyance and it is free from irritating redundancy. At the end of most chapters are given pertinent references to source material.

It is inevitable that much of the subject matter is based on, or at least compared with, surgical experience in the last war, the lessons of which we have had a chance to analyze. It is, perhaps, regrettable that with fortunately limited opportunities the writers have not been able to give a final answer to questions arising from the changing philosophy of the care of wounds and chemotherapy. The book is written by men actually engaged in caring for those injured by all destructive methods of totalitarian warfare and they can give only what opportunity has offered them to learn. The final conclusions will be written later.

Methods, apparatus, technics and surgical philosophy are given in the most vivid and practical style, aided by more than five hundred illustrations. These range from helpful line drawings to beautiful colored reproductions of wounds. The latest views on shock, burns, chemotherapy, oxygen therapy, transfusion and preparation of plasma, and the use of heparin, are included and well presented. It is impossible to choose for special praise or censure any of the sections, since all are up to date and authoritative.

The second volume will cover problems associated with neurosurgery, with sections on administration, transport and organization of hospitals and its services.

The book is easy to handle, the pages and print make it easy to read. It is a volume for the library and not for the field. One must respect the opinions of the writers because of past achievements, and they have written now amid changing methods and in the face of new and dreadful problems. The book can be read with interest and profit by surgeons familiar with and skilled in the care of traumatic lesions, although much of the subject matter will be elementary to them. It will prove a veritable necessity to the surgeons whose efforts have been confined to the usual civilian practice but whose activities may be transferred to the care of trauma in the mass. War minimizes specialization; therefore, this book is heartily recommended to any one interested in the care of the injured, whether student, intern, military or civil surgeon, surgical specialist or general surgeon. It gives the views of today; the truth will crystallize tomorrow.

The Therapy of the Neuroses and Psychoses: A Socio-Pscho-Biologic Analysis and Resynthesis. By Samuel Henry Kralnes, M.D., Associate in Psychiatry, University of Illinois College of Medicine, Chicago. Cloth. Price, \$5.50. Pp. 512. Philadelphia: Lea & Febiger, 1941.

Another textbook of psychiatry appears on the American book list and another disappointment. This is one more psychobiology with all the wordiness that usually goes into such a product. The usual orthodox categories are described in the usual terms of stress and faulty habits, of constitution and specific attitudes or reaction patterns. The author's language becomes so involved that one can only accuse him of thoroughness to confusion rather than error. When it comes to therapy, which is the real object of discussion, the reader is amazed at the naïveté expressed: "As the discussion reveals specific attitudes or reaction patterns which are in themselves unhealthy and which have contributed to the emotional instability of the patient, the physician enlists the cooperation of the patient in ascertaining the origin of the particular attitude. When the cause, or more usually the causes, are determined, the patient's reactions to the causes is discussed and the better attitudes which should have been used are suggested in order to remove any resentment still existing in the unconscious" (p. 127). The author has not one single reference to another book or journal except, after stating that psychoanalysis may appear as fantastic nonsense (p. 424), he gives a lengthy abstract from a textbook of psychoanalysis in such garbled fashion as to convince the unknowing reader that it is nonsense, as Kralnes believes. If it has as yet not become clear, the reviewer emphatically believes the book can only confuse and disorient the reader who has curiosity regarding the field of psychiatry.

The Heart in Pregnancy and the Childbearing Age. By Burton E. Hamilton, M.D., Cardiologist, since 1921, to The Boston Lying-in Hospital, Boston, and K. Jefferson Thomson, M.D., Associate Physician, Metropolitan Life Insurance Company Sanatorium, Mount McGregor, New York. With a section entitled *Delivery and Obstetrical After-Care of Cardiacs*. By Frederick C. Irving, M.D., F.A.C.S., Professor of Obstetrics, Harvard Medical School, Boston. Cloth. Price, \$5. Pp. 402, with illustrations. Boston: Little, Brown & Company, 1941.

This is a comprehensive book on every aspect of heart disease that may occur in women during pregnancy and the childbearing age. The book is divided into three parts, the first of which deals with the cardiac in pregnancy, the second takes up physiology of the circulation in normal pregnancy and in pregnant women with heart disease and the third comprises the heart diseases in pregnancy and the childbearing age. Hamilton, who practices as a general cardiologist, has been in charge of the heart clinic at the Boston Lying-in Hospital for the last twenty years and Thomson spent three years as full time research worker at the same hospital, devoting a great deal of time to physiologic studies of the heart and circulation. The authors are therefore distinctly well qualified to write a book on heart disease in pregnancy. The book is based chiefly on the authors' extensive experience comprising 850 cardiac patients among 48,190 pregnant women (1.7 per cent) but they frequently refer to the studies of other investigators. The section dealing with the delivery and obstetric after-care of cardiac patients was written by Frederick C. Irving, professor of obstetrics at the Harvard Medical School. The book is easy to read and

contains numerous case histories which are highly instructive. The type is clear and there is a well prepared index. This book contains so much valuable data not only of the physiology and pathology of the heart but also of the proper diagnosis and management of heart disease in pregnant and puerperal women that every cardiologist, internist and obstetrician should be familiar with its contents.

The Doctor and the Difficult Child. By William Moodie, M.D., F.R.C.P., D.P.M., Medical Director, London Child Guidance Clinic and Training Centre. Cloth. Price, \$1.50. Pp. 214. New York: Commonwealth Fund; London: Oxford University Press, 1940.

This is a book to be welcomed by pediatricians, general practitioners and intelligent laymen, for it lives up to the opening statement of the author's introduction: "This is not a scientific treatise; it is rather an informal discussion of fundamental disturbances of behavior or personality in children and how they can be recognized, investigated and treated." The well organized text is uncumbered by medical terms and theories of treatment. Throughout, the author stresses the necessity of determining the underlying cause of the disturbance and the importance of work, security and affection in maintaining a healthy child. Numerous case histories amplify each point. The pediatrician and general practitioner will find the suggestions for diagnosis through interpretation of the child's play, drawing and conversation valuable in their own work. Laymen will not only learn what to expect of normal children but will gain an excellent foundation for understanding their children and for further reading.

O prodolzhitelnosti zhizni heterogennykh i gomogennykh eritrotsitov v krovyanom rusle rettsiplenta; eksperimentalnoe issledovanie. [By] N. S. Voronov. [Duration of Vitality of Heterogenous and Homogenous Erythrocytes in Blood Stream of Recipient; Experimental Study.] Paper. Price, 4 rubles. Pp. 96, with 7 illustrations. Rostov on Don: Rostovskoe Oblastnoe Vedomstvennoe Izdatelstvo, 1940.

The monograph deals with an experimental attempt to determine the survival of the transfused red blood cells in the circulation of the recipient. Experiments were made with both heterogenous and homogenous bloods. The method of investigation developed by the author is based on the well known phenomenon of Bordet that serum of an animal of a certain species when immunized with erythrocytes of an animal of another species acquires the property of dissolving erythrocytes of the latter only. The method allows of both the qualitative and the quantitative determination of the erythrocytes in the blood circulation of the recipient. Transfused heteroerythrocytes are eliminated rapidly, although wide differences were found for different species. Homoerythrocytes of the citrated blood, on the other hand, survive up to two months. The erythrocytes of conserved blood are eliminated from the circulatory blood of the recipient as early as the fifth day. This is a worth while contribution to the general subject of blood transfusions. It is in Russian and does not contain the usual summary in any of the more readily accessible languages.

Lectures on Diseases of Children. By Sir Robert Hutchison, Bart, M.D., F.R.C.P., Consulting Physician to the London Hospital, London, and Alan Moncrieff, M.D., F.R.C.P., Physician to the Children's Department, Middlesex Hospital, London. Eighth edition. Cloth. Price, \$6.75. Pp. 471, with 107 illustrations. Baltimore: William Wood & Company, 1940.

This edition has been revised and brought up to date by Dr. Alan Moncrieff. The chapters on infant feeding and artificial feeding are entirely new. The chapter on digestive disorders of infancy has been revised, and there has been extensive change in the chapter on behavior problems in childhood. As originally constituted, this book consisted of lectures delivered as a systematic course in pediatrics. As such it expressed one man's views and was necessarily to some extent dogmatic in character. It is the opinion of the reviewer that, in the revision of the book by the co-author, other views and a limited citation of the literature might have benefited the student for whom the book is intended. This is a pedagogic question which must be answered by the individual teacher according to the previous preparation and advancement of the student body. The book is excellently illustrated and well printed, has a complete index, and will serve its purpose as an aid to the student and teacher of pediatrics.

Magic in a Bottle. By Milton Silverman, Ph.D. Cloth. Price, \$2.50. Pp. 332. New York: Macmillan Company, 1941.

This book does for the chemical trail breakers what De Kruif's "Microbe Hunters" did for the bacteriologic pioneers. The author, by virtue of his experience in scientific circles on the Pacific Coast especially in connection with the Golden Gate International Exposition, is well qualified to write it and has done so ably. The book deals with the discovery and introduction of morphine and quinine, digitalis, cocaine, the antisyphilis drugs, acetylsalicylic acid, barbituric acid and its derivatives, the vitamins, the hormones and the sulfanilamide group. The book is written in the best tradition of popular science writing. All the heroes are struggling young men with big ideas which are scornfully rejected by scientific stuffed shirts. Right always triumphs, which makes for the progress of science and also makes excellent reading. Much of the commendably accurate but regrettably dull scientific writing for the public could be greatly improved with a little touch of human nature and drama so interestingly supplied in this book. Those who read it will know much more about the medicines their doctor uses and in the process of learning they will be agreeably diverted and pleasantly stimulated.

Tumores primitivos malignos broncopulmonares: Cáncer, sarcoma, linfogranuloma. Por Julio Palacio, profesor adj. de clínica médica de la Fac. de med. de Buenos Aires, y Egidio S. Mazzel, Prof. adj. de clínica médica de la Fac. de med. de La Plata. Paper. Pp. 401, with 129 illustrations. Buenos Aires: El Ateneo, 1940.

The great increase in the occurrence of cancer of the lung in the last few years has offered a large material for clinical and pathologic study. This volume emphasizes especially the clinical side and in addition to carcinoma includes sarcoma and a short section on Hodgkin's disease of the lung. It furnishes an excellent survey of the subject from this special aspect. There are some well reproduced colored plates showing the gross aspects of interesting types of lung tumors, and photomicrographs of the various forms of carcinoma of the lung. What is most interesting is a large series of roentgenograms of the lung lesions, which are well reproduced. There is a complete bibliography, which is on the whole accurate as far as has been verified, though the proofreading of names and some foreign words could be improved. For those who are familiar with Spanish this is a useful treatise.

Die Appetitlosigkeit im Kindesalter. Von Julius Surányi, Oberarzt am Stefanie-Kinderspital, Budapest. Paper. Price, 6 Swiss francs. Pp. 128. New York: Nordmann Publishing Company, Inc.; Basel: S. Karger, 1940.

This small monograph on anorexia in childhood is a reprint from *Annales Paediatrici* (155:177 [July-Aug.], 345 [Sept.] 1940). The etiology of anorexia is considered from an organic, a nutritional and a psychic basis, and the prophylaxis of anorexia is discussed. Specific therapy for anorexia includes dietary instructions, vitamin therapy and treatment of diminished digestive secretion. In a disease condition the causes of which are so diverse, one realizes that no single specific therapeutic agent is universally applicable. Among the remedies recommended to stimulate appetite are iron, copper and liver for anemia; arsenic, strychnine and other tonics are also recommended, and the use of insulin is included. Finally, two pages are devoted to psychic therapy. The author has presented a review of the literature, although he has not presented any new or startling discoveries as to the nature and treatment of the condition.

You . . . Might Like Pharmacy as a Career: An Occupational Brief Prepared by Western Personnel Service Under the Sponsorship of the University of California as a Report of Works Projects Administration, Official Project No. 65-1-07-2258. Paper. Price, 25 cents. Pp. 14. Pasadena, California: Western Personnel Service, 1940.

On the inner title page appears the additional information that this "brief" is a report of the Works Projects Administration, Official Project No. 65-1-07-2258. The brochure sets forth in glowing language the opportunities and advantages of pharmacy as a vocation. The somber side of the picture is discreetly veiled.

Sella turcica und Konstitution: Versuch einer Sella-größen- und Formdeutung innerhalb konstitutionsmedizinischer Gefüge. Von Dr. med. Hans-Otto Martin. Eine Gemeinschaftsarbeit aus der Charité Berlin. Boards. Price, 5.70 marks. Pp. 107, with 9 illustrations. Leipzig: Georg Thieme, 1941.

This small monograph has for its purpose the correlation of the shape and size of the sella turcica, as seen in roentgenograms taken under standard conditions, with various constitutional states. It is based on the statement (p. 10) that in view of the facts that no one gland of internal secretion can be regarded separate from the entire endocrine system and that the hypophysis occupies a central position in this system we are justified in examining the sella turcica not only in hypophysial disorders but in other endocrine and neuropsychiatric syndromes as well. The author attempts to draw correlations between sellar structure and disturbances of the development of the capillary bed in myxedema. Efforts at finding some significance in so-called bridging of the sella turcica (pp. 26-28) were not very successful. It was not possible to correlate any particular constitutional type with any particular form or size of the sella, but as generalizations the author was able to say that in tall and acromegalic persons the sella is usually large and round, in the asthenic and thin it is usually small, whereas in those with retarded growth the sella turcica may be either large or small. The results of this investigation presented here cannot be regarded as of far reaching significance.

Principles of Abnormal Psychology: The Dynamics of Psychic Illness. By A. H. Maslow, Ph.D., and Béla Mittelmann, M.D. Cloth. Price, \$3.50. Pp. 638. New York & London: Harper & Brothers, 1941.

This is a good year for students of psychology, for here is at last a dynamic, vibrant textbook of psychology that cannot be ignored by academic teachers. In this volume human conduct, motivation and dynamics are discussed in relation to actual patients in real situations. The book is written for college students, but its brilliant, accurate yet lucid expositions indicate its usefulness to medical students and general practitioners. No one point of view or school is followed, for the interests and background of the authors are broad and thorough. There is an excellent index and glossary; extensive references and suggested readings are profuse and interpolated throughout the text. The headings and subdivisions of the book make reference work extremely easy. This is a book that can be unequivocally recommended for those interested in abnormal psychology.

On Nicotinic Acid: Especially Methods for Its Quantitative Estimation in Organic Material. By Erik Bandier. Translated by Dr. P. G. Lund. Denne Afhandling er et af det lægevidenskabelige Fakultet antaget til offentlig at forsvares for den medicinske Doktorgrad. København, 1940. Paper. Price, 10 Danish kroner. Pp. 165, with 8 illustrations. Copenhagen: Ejnar Munksgaard, 1940.

This book consists largely of a summary of the experimental work conducted by the author during the past three years. The first chapter gives a historical account of nicotinic acid and a description of its clinical and pharmacologic properties as well as its use in therapy. A rather complete summary of the other pyridine derivatives found in the human and animal organisms follow in the second chapter, but most of the remainder of the book gives the detailed results obtained from nicotinic acid determinations on biologic material by the cyanogen bromide method. The values given for the nicotinic acid content of various tissues check fairly well with the few figures available in the literature. The author points out that nicotinic acid is excreted partly as free nicotinic acid and partly in combined forms. After ingestion of 90 mg. of nicotinic acid by fasting healthy persons only 15 per cent was recovered in the urine. Similar results have been reported by other workers. The entire book gives emphasis to the limited amount of knowledge concerning the metabolism of nicotinic acid in the human body and to the great need for much more work.

Feeding Our Old Fashioned Children: A Background for Modern Mcallimes. By C. Anderson Aldrich, M.D., Associate Professor of Pediatrics, Northwestern University Medical School, Chicago, and Mary M. Aldrich. Cloth. Price, \$1.75. Pp. 112, with 6 illustrations. New York: Macmillan Company, 1941.

Probably the most common problem presenting itself in pediatric practice is that of the child who will not eat. This book has been prepared in an effort to aid parents in the solution of that situation. The first ten chapters of the book

are devoted to presentation of the problem and discussion of the etiologic factors contributing to the refusal of food. The last chapter is concerned with the treatment of the child afflicted with anorexia. Unfortunately, parents do not become aware of the problem until it is well established; hence it would seem that more material should be devoted to the unraveling of the situation rather than to the discussion of the elements responsible for its inauguration. The theories and ideas presented appear sound. On the other hand, it would appear that the field of usefulness of this book is somewhat limited.

Dyke's Automobile and Gasoline Engine Encyclopedia: The Elementary Principles, Construction, Operation and Repair of Automobiles, Gasoline Engines and Automobile Electric Systems; Including Trucks, Tractors, Motorcoaches, Automotive Diesel Engines, Aircraft Engines and Motorcycles. Simple, Thorough and Practical. By A. L. Dyke. Nineteenth edition. Cloth. Price, \$6. Pp. 1,244, with illustrations. Chicago: Goodheart-Willeco Company, Inc., Publishers, 1941.

As the title indicates, this book of nearly fifteen hundred pages is encyclopedic in its information about automobiles and gasoline engines. In compiling the data the author had in mind the car owner, the repair man and the student. He discusses the underlying scientific principles involved in each subject and makes the book practical in various ways, including thousands of pictures, plans, diagrams and charts, some in color. There is a section on "Trouble Shooting" with charts in color to enable the reader to locate quickly trouble about his car. The working principles of trucks and tractors also are illustrated and discussed. There are special instructions on testing and adjusting various parts of the automobile. This edition has been revised and enlarged. The author has endeavored to make the information readily available by including thousands of lines of index. The book has been encumbered somewhat, however, by the inclusion of two different indexes, an addendum and various folded inserts. There are many practical suggestions which will enable the reader to meet emergencies and to maintain a car.

Photodynamic Action and Diseases Caused by Light. By Harold Francis Blum, Ph.D. American Chemical Society Monograph Series, No. 85. Cloth. Price, \$6. Pp. 309, with 50 illustrations. New York: Reinhold Publishing Corporation, 1941.

This volume is a treatise on photodynamic action and radiation, both artificial and natural, on the human being and on animals. It deals with diseases produced in men and in animals by radiation. The book contains a generous review of the literature on this rather restricted branch of medicine and embraces material contributed by the author himself especially regarding the use of radiation in cancer. The volume is in four parts and has a total of twenty-four chapters. Part one, the introduction, deals with the physical nature of radiation and its biologic effects. The second part is on photodynamic action. Diseases produced by light on domestic animals and on man are dealt with in parts three and four, and this material should be of interest to the dermatologist. Mathematical and chemical equations are sprinkled here and there, together with a goodly number of tables and charts. One chapter is given over to the effects of long exposure to sunlight and its possible cause of cancer. For the skin specialist this work should be on the shelves of his library, but for the general practitioner it is recommended as a reference book.

Neurology: Lectures for Medical Students and General Practitioners. By Knud H. Krabbe, M.D., Chief-Physician, the Department of Neurology, Kommunehospitalet, Copenhagen. Translation by Gerda Seidelin, M.B. Paper. Price, 12 Danish kroner. Pp. 390, with 9 illustrations. Copenhagen: Ejnar Munksgaard; London: Oxford University Press, 1941.

The author is a distinguished Danish neurologist who has for a quarter of a century lectured to medical students. In this book he presents his lectures in their original form, in which the material is divided according to etiology rather than according to topography or in syndromes. It is a delightful little book to peruse, lucid in its descriptions, concise and yet fairly comprehensive for the needs of the student. Unfortunately the author has chosen to include psychiatric disorders, in which he gives a poor account of himself. Only Scandinavian literature is quoted. There are few illustrations, but an adequate index is appended.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

CORONARY THROMBOSIS AND VALVULAR HEART DISEASE

To the Editor:—Are there any statistics available as to the frequency of coronary thrombosis in persons with valvular disease, of the heart due to rheumatic fever?

M.D., New York.

ANSWER.—Adequate statistics of the incidence of coronary thrombosis in valvular disease of the heart have not been found. There are a number of reports which suggest that the incidence is low. In a paper by White and Jones on heart disease and disorders in New England (*Am. Heart J.* 3:302 [Feb.] 1928) there was an etiologic analysis of 3,000 cardiac patients. Of the 3,000 there were 956 who were rheumatic and only 18 of these had an additional diagnosis of coronary disease, but there was no statement as to how many had coronary occlusion. In a paper by Davis and Weiss on rheumatic heart disease (*ibid.* 7:146 [Dec.] 1931) it is stated that in 474 necropsies only 41 cases of rheumatic heart disease had an association with hypertensive coronary disease, coronary disease or severe anemia, but there is no statement as to how many of the cases showed coronary occlusion. There would seem to be few.

Coombs in his book on rheumatic heart disease had little or nothing to say about the complication of coronary disease, and that is true of most papers on the subject.

There is more information from the point of view of coronary disease. There again the incidence is low. For example, among 145 cases of coronary thrombosis reported by S. A. Levine in his monograph in 1929 there were no instances of true mitral stenosis and only 1 of aortic stenosis. He spoke, however, of having seen 1 case of coronary occlusion and definite rheumatic mitral stenosis not in his original group of coronary thrombosis. There were 14 cases with some degree of stenosis of the leaflets of the aortic valve as manifested by slight fibrosis, thickened atheromatous plaques or calcification. Similar changes were found in 4 cases in the mitral valve and in 1 case in the pulmonary valve.

In some unpublished data at one hospital, among 97 autopsies in cases showing acute coronary thrombosis there was only 1 with rheumatic heart disease. There was another with a calcareous aortic stenosis. In another group of 78 autopsies at the same hospital in cases of old myocardial infarction there was 1 case of rheumatic heart disease. In 31 cases of old coronary thrombosis without infarction there were 2 cases of aortic stenosis.

FASTING BLOOD DONORS—POOLING OF PLASMA OR SERUM

To the Editor:—I would appreciate some information on the following questions: 1. Is there any experimental or clinical substantiation for the statement that transfusion of "blood from a donor after ingesting food is followed by a transfusion reaction which is not to be expected in a fasting donor?" 2. In the transfusion of blood plasma or serum, are typing and cross matching necessary? Does it make any difference, in answering this question, whether the blood is from one donor or is pooled?

Gabriel Vandama, M.D., Habana, Cuba.

ANSWER.—1. If by "transfusion reaction" is meant a rise in temperature with or without a chill, there is no basis for the statement quoted. It is true, however, that a patient is more apt to have an urticarial reaction after the use of blood from a donor who has just eaten, provided the patient is allergic to one of the foods ingested by the donor. For this reason the routine use of fasting donors for transfusion has been advocated. If the blood is to be used for preparing plasma, the product will be much more turbid if the blood is taken from a donor after a meal than if taken from a fasting donor. Aside from the esthetic objections, it is impossible to recognize with the naked eye the presence of bacterial growth in turbid plasma.

2. The consensus is that if plasma (or serum) is prepared from individual samples of blood it is preferable to use only plasma of the same group as the patient's, since the indiscriminate use of untyped plasma would have the same objections as the indiscriminate use of the "universal donor." To eliminate the undesired isoagglutinins, several procedures have been advocated. Pooling the blood before separation of the plasma, as

recommended by certain investigators (Edwards, F. R.; Kay, James, and Davie, T. B.: *The Preparation and Use of Dried Plasma for Transfusion, Brit. M. J.* 1:377 [March 9] 1940), while efficient, has the disadvantage that the interaction between bloods of different groups may cause hemolysis, and hemolyzed plasma may cause a reaction. Therefore the approved procedure is to pool the plasma after separation from the blood. Best results are obtained with rather large pools containing ten or more samples, and with such pooled plasma the group of the patient can be disregarded. Pooling serves to diminish the titer of the isoagglutinins by two mechanisms (Levinson, S. O., and Cronheim, Anny: *Suppression of Iso-Agglutinins, THE JOURNAL, May 25, 1940, p. 2097*) (a) by simple dilution and (b) by neutralization of the isoagglutinins by group substances present in solution. With regard to the second mechanism, it is probably only minor, since the concentration of group substances in serum is low, in contrast, for example, to the concentration in saliva. In this connection Witebsky, KlenDshoj and Swanson (*Preparation and Transfusion of Safe Universal Blood, THE JOURNAL, June 14, 1941, p. 2654*) have recommended the addition of purified solutions of group substances A and B to blood of group O which is to be used for persons whose blood does not belong to group O, in order to neutralize the anti-A and anti-B agglutinins present in the blood. The routine addition of solutions of group substance to plasma would appear to make unnecessary not only grouping of the plasma but also pooling. In conclusion it may be remarked that in an emergency when plasma is at hand which has been prepared from only a single sample of blood this can probably be used with safety regardless of the group, provided the plasma is made to run into the vein slowly, since the extremely slow introduction of foreign agglutinins can be taken care of by the body without harm to the patient.

INDIGESTION AND SYNCOPE

To the Editor:—On Sept. 6, 1940 a patient fell while at work and fractured his skull. Roentgen examination showed a linear fracture at the base in the left occipital region. He is 73 years old and has been in good health, having worked at his present job for fifteen years. He fainted once at his work twenty years ago. His blood pressure is average for his age. At the time he fell he was standing at his bench brushing a hat which had been dyed the day before and was still somewhat wet. The case is before the compensation commissioner. The insurance company is attempting to prove that because the man had eaten cucumbers for supper the night before and had complained of some "indigestion" on arriving at the shop he fainted because of his indigestion, fell and fractured his skull. The insurance company called the shop doctor as its witness, and he testified that indigestion is a common cause of fainting. I was surprised at this, as I have never seen such a case. The patient ate cucumbers two or three times a week and suffered no ill effects. The accident occurred at 8:30 a. m. Would it be reasonable to expect cucumbers eaten for supper to cause indigestion the next morning? Can you give me any figures on the incidence of fainting among people with indigestion or supply me with references? Will steady focusing of the eyes of an old person with moderate arteriosclerosis (i. e. on near objects) cause vertigo or fainting? Eric Ernst Stietzel, M.D., South Norwalk, Conn.

ANSWER.—The fact that the patient had previously eaten cucumbers two or three times a week without ill effects suggests that they were not the primary cause of the "indigestion." The role played by the cucumbers is problematic. It is not clear when the dyspeptic symptoms first occurred in relation to the evening meal. If the onset was within a few hours and the symptoms persisted until the next morning, the cucumbers may have been a contributory factor. If the onset, however, was about twelve hours later, the "indigestion" may well have occurred had no cucumbers been eaten the previous night.

Figures cannot be given for the incidence of fainting in those with digestive disturbances. "Indigestion" is a vague descriptive symptom which may result from a variety of digestive diseases and disturbances, as well as from numerous conditions outside the digestive tract, such as coronary occlusion, migraine or a hyperactive carotid sinus reflex (Eusterman, G. B., and Balfour, D. C.: *The Stomach and Duodenum, Philadelphia, W. B. Saunders Company, 1935, pp. 111-137*). When syncope occurs it may be coincidental or caused by the same organic condition that is responsible for the "indigestion." In the latter event the incidence of fainting depends entirely on the nature of the primary disease.

When demonstrable organic disease is not found after a thorough physical, laboratory and roentgenologic examination to explain satisfactorily the "indigestion," it is often attributed to a functional digestive disturbance. Syncope may be coincidental in such persons or it may occur during attacks of acute nonspecific enteritis with severe abdominal cramps and diarrhea. Vertigo and fainting attributed to eyestrain often appear under circumstances in which it is difficult to evaluate the etiologic importance of the eyestrain. The type and degree of

refractive error, if uncorrected, must be taken into consideration. Standing in one position for a time is not only a predisposing factor but may in itself result in syncope. Hunger, fatigue, malaise and various debilitated states also may produce syncope. When a number of these factors are present at the time of fainting, as was apparently the case in the instance cited, it is often difficult, if not impossible, to say which was the precipitating cause.

REACTION TO PITRESSIN

To the Editor:—A woman aged 51 was in excellent general condition five days after removal of a stone from one kidney pelvis except that she was somewhat distended with gas. Laxatives, enemas and the colon tube gave no appreciable relief. Ten units of pitressin was given hypodermically, followed fifteen minutes later with a soap-suds enema. The results were moderately beneficial and there was no deleterious effect. About ten hours later, as the patient was again somewhat distended with gas, the same orders were repeated. Within a few minutes after administration of the pitressin the patient became pale, felt faint and expelled a large amount of gas. The enema was given a few minutes later and was promptly expelled with a small amount of soft stool and a great abundance of gas, which left the abdomen completely relieved of distention. The patient was seen a few minutes later and was found to have a severe pallor, slight dyspnea with respiration about 30, pulse and heart rate 100, and blood pressure 130 systolic and 70 diastolic. The patient stated that she felt faint. The general picture was not such as to cause alarm except for the deathlike pallor and the fear that the mild shock—if such it was—would become progressively worse. The foot of the bed was elevated and 500 cc. of 10 per cent dextrose solution with 10 units of insulin was promptly started intravenously but administered slowly. Within a few hours the patient's condition was normal. Please explain the action of pitressin and why this second administration caused such a severe reaction when a like amount given ten hours earlier caused no reaction at all. Did the rapid collapse of the bowel cause a splanchnic congestion?

Andy Hall Jr., M.D., St. Louis.

ANSWER.—Pallor is frequent following the administration of pitressin. Kirklin and Seedorf (*Ann. J. Roentgenol.* 42:811 [Dec.] 1939) found it in 81 per cent of patients given pitressin preliminary to cholecystography. The pallor in itself is a manifestation of vasoconstriction in the skin. The vasoconstrictor effect, however, is usually generalized, leading to a variety of symptoms in addition to those resulting from increased bowel activity. The total reaction, therefore, may at times cause alarm. Because the pallor is often so striking, it may suggest that the patient is in shock. This, however, is rarely if ever the case.

Pitressin pallor gives little indication of the severity of the reaction. In fact, it is difficult to evaluate pitressin reactions at the time they occur. The symptoms, however, almost invariably subside spontaneously within a few hours and there is no apparent deleterious after-effect.

A number of competent observers have found that pitressin often causes a decrease in blood pressure. The mechanism of the simultaneous generalized vasoconstriction and fall in blood pressure is not entirely clear. There is evidence to indicate that the coronary arterioles constrict with a consequent decrease in the minute volume output of the heart. This may explain the seemingly paradoxical action of pitressin, but other factors are probably involved as well. The fall in blood pressure is usually not marked when pitressin is given intramuscularly or subcutaneously and is of interest chiefly because the term "pressor principle" is misleading in this respect.

Melville (Pressor and Oxytocic Fractions of Posterior Pituitary Extract: Comparative Effects on Blood Pressure and Intestinal Activity, *THE JOURNAL*, Jan. 11, 1936, p. 102) found that a marked drop in blood pressure and collapse occurred in unanesthetized dogs following the intravenous administration of moderate amounts of the pressor constituent of posterior pituitary. This effect would be lessened or abolished when the oxytocic principle was given simultaneously in sufficient dosage. These observations may explain some of the apparently conflicting reports in the literature.

Great variation in the response of the same individual to the same dose of a biologic preparation is rather common, and pitressin is no exception. In the clinical use of pitressin a "maximal" effect is seldom obtained. It is not clear what determines the degree or type of reaction. Melville found pitressin to be consistent in its effect in unanesthetized dogs when given intravenously. When administered by other routes, however, the effects were so variable that no definite conclusion could be reached.

The rapid collapse of the bowel might conceivably have been a factor; however, this seems unlikely in view of the fact that the same type and degree of reaction is frequently seen in patients without evidence of unusual abdominal distention.

It would appear, therefore, that the patient under consideration experienced a reaction to pitressin within the limits of the reactions frequently seen.

HYPERTENSION AND POSSIBLE CUSHING'S SYNDROME

To the Editor:—A young woman complains only of a slight increase in the menstrual flow and slight nervousness. She has hypertension, the cause of which has not been determined. The possibility of Cushing's syndrome, possible pituitary hyperactivity, anterior or posterior, or of some condition for which a remedy may be had, is considered. She has had the usual diseases of childhood but not scarlet fever or diphtheria. At the age of 18 the right ovary was found to be cystic and was removed to correct a menorrhagia. The blood pressure was not recorded at that time, but the urine was normal. The patient has no other complaints. She is well developed and weighs 129 pounds (58.5 Kg.). The face is of full moon type. This effect has somewhat increased during the last year with the patient's gain in weight from 115 pounds (52 Kg.) but there is no suggestion of bull neck. The blood pressure is 170 systolic and 114 diastolic, the pulse rate 122, the respiratory rate 20 and the temperature normal. The eyes are prominent but not exophthalmic. The thyroid is not palpable. The lungs are normal. The heart is not enlarged. There is a suggestive systolic shock but no thrills. The aortic second sound equals the pulmonic second. There is a definite presystolic roughness followed by a loud overactive first sound which strongly suggests mitral stenosis. On fluoroscopy there is no enlargement of the left auricle or any other chamber; the aortic knob is present. There is no prominence of the pulmonary conus. The abdomen is normal except for the operative scar. The liver and spleen are not palpable. The secondary sexual characteristics are well developed. While the heart sounds are strong and overactive, the pulse is rather weak but definitely palpable bilaterally. It is regular. The blood pressure in both arms is 170 systolic and 114 diastolic and in both legs at the popliteal fossae 200 systolic and 140 diastolic. Ophthalmoscopic examination reveals only slight spasm of the retinal arterioles. The radials are not definitely sclerotic. The blood count is normal, as is also the urinalysis. Exton's sugar tolerance studies revealed a fasting blood sugar of 83 mg.; thirty minutes after 50 Gm. of dextrose the blood sugar was 110 mg.; 50 Gm. more of dextrose was administered at this time and one-half hour later the blood sugar was 109 Gm.; one hour after this the blood sugar fell to 69 Gm. (checked twice). Basal metabolic studies revealed plus 16 and plus 19 per cent. After two weeks of bed rest and compound solution of iodine the basal metabolic rate fell to minus 5, but the pulse remained the same, 120 both at the office and while at rest at home. The heart tones have not changed, and the overactivity is still present with the same pulse of rather poor volume. With one exception of a blood pressure of 150 systolic and 90 diastolic the pressure remains between 170 systolic and 114 diastolic and 180 systolic and 120 diastolic. On exercise the heart rate rose to 136 and returned to 120 after one minute. There was no undue respiratory discomfort. Friedman's pregnancy test was negative. The electrocardiogram was normal except for the tachycardia and low R_s. The intravenous diodrast test was unsatisfactory. The roentgenograms showed no osteoporosis of the pelvic bones as one finds in Cushing's syndrome. Please suggest diagnosis and treatment.

David Scheinberg, M.D., Memphis, Tenn.

ANSWER.—Hypertension in a young woman is usually due to a chronic glomerulonephritis, pyelonephritis, polycystic kidneys, coarctation of the aorta or the condition called "essential hypertension" because of the absence of demonstrable primary disease. Transitory emotional hypertension and menopausal hypertension are apparently excluded in this case. The normal urine and renal function tests rule out chronic nephritis and pyelonephritis, while the elevated systolic blood pressure in the popliteal arteries eliminates coarctation of the aorta as a diagnostic possibility. Polycystic kidneys, unilateral atrophic pyelonephritis and a fair sized tumor of the adrenal cortex could scarcely be excluded without a retrograde pyelogram. Therefore this procedure is definitely indicated, especially in view of the unsatisfactory intravenous pyelograms. The masculinizing tumor of the ovary, or arrhenoblastoma, has little in its favor in this case.

There is insufficient basis for a diagnosis of Cushing syndrome. The result of the dextrose tolerance test and the normal menstruation speak against it. For the sake of completeness, it would be worth while to determine the value of the serum sodium, potassium, bicarbonate and chloride. A high serum sodium and bicarbonate content with a low potassium level suggest hyperfunction of the adrenal cortex. Diminished concentration of urinary chloride—below 0.4 per cent—in the last four hours of a fifty-two hour period during which the patient is on a diet containing only 1.5 Gm. of sodium chloride and 4 Gm. of potassium but also receiving 10 Gm. of sodium chloride in capsules twice daily for two days, with the fluid intake at 20 cc. per kilogram of body weight for the first two days and only 5 cc. per kilogram during the four hours of the urine collection, would be supporting evidence for a Cushing syndrome (Cantarow, Abraham: *Science* 90:375 [Oct. 20] 1939). Probably further observation of the patient for six months or a year will allow the development of more definite signs or the establishment of a diagnosis of "essential" hypertension.

Treatment depends on the diagnosis. Sufficient evidence for tumor of the adrenal cortex or arrhenoblastoma warrants surgical exploration. General hygienic measures, mild sedation with phenobarbital and prevention of further gain in weight are indicated, in addition to any necessary symptomatic treatment.

SIGNIFICANCE OF ERYTHROCYTE SEDIMENTATION RATE

To the Editor:—1. What is the significance of a change from normal in sedimentation rate in the blood of an adult? 2. What effect does an acute suppurative process such as an acute abscess have on the sedimentation rate? 3. What effect does a chronic infective process such as chronic tonsillitis or abscessed teeth have on the sedimentation rate?

M.D., Wisconsin.

ANSWER.—1. An increase in the sedimentation rate of red blood cells is usually correlated with an abnormal increase in the concentration of globulins of the blood plasma, especially plasma fibrinogen. An abnormal elevation in the concentration of plasma fibrinogen and in the sedimentation rate is one of the most frequent responses of the body to a variety of noxious stimuli such as tissue inflammation or destruction, whether traumatic, chemical, bacterial or neoplastic. It may be increased after the injection of foreign protein, small doses of liver poisons and damage from roentgen rays. Physiologically, fibrinogen production is increased in normal pregnancy. Occasionally the sedimentation rate is increased above normal associated with an elevation of the concentration of serum globulins in such diseases as cirrhosis of the liver, multiple myeloma and chronic infection. An abnormally slow sedimentation rate is not a satisfactory measure of plasma proteins and can be interpreted only as compatible with normal. For a more complete discussion of the subject, see Ham, T. H., and Curtis, F. C.: *Medicine* 17:413 and 447 (Dec.) 1938.

2. An acute suppurative process usually produces an elevation in the sedimentation rate and in the plasma fibrinogen level after the third or fourth day, especially if there are generalized manifestations from the abscess. A localized abscess may not increase the sedimentation rate.

3. In general, chronic inflammatory processes such as chronic tonsillitis or abscessed teeth do not produce an elevation of the sedimentation rate. So-called focal infections influence the sedimentation rate more or less in proportion to the nature and severity of the pathologic process. Chronic localized infections may have no influence, whereas chronic infections characterized by exudative inflammation such as pelvic inflammatory disease, tuberculosis and chronic bronchitis may cause significant increase in both plasma fibrinogen and the sedimentation rate. For further details, see Wintrobe, M. M.: *M. Clin. North America* 21:1537 (Sept.) 1937.

HYPERSENSITIVITY TO SOAPS

To the Editor:—An intelligent housewife, aged 42, appears to be sensitive to alkalis. Soaps used in washing dishes or for any other purpose irritate the nose and eyes, produce an eczematous rash, and once appeared to be the cause of a severe conjunctivitis difficult to overcome. If washing is done in the basement and the woman stays in another part of the house, she is still distressed. She has tried almost all brands of soap and finds little difference in them, but chip soaps give less trouble than bar soaps and Lux chips somewhat less than other kinds. A consultant specializing in allergy advised large doses of vitamins A and C. The treatment was used two months with doubtful results. Has any treatment been devised that might be helpful for this condition?

Charles W. Carter, M.D., Clinton, Ill.

ANSWER.—Hypersensitivity to soaps may be of two types: 1. Soaps may act as primary irritants for some skins and mucous membranes, largely because of their alkali content. 2. There may be a specific hypersensitivity due to one or more of the various ingredients of soap, especially cottonseed and flaxseed oils, used in the manufacture of some soaps. The advice given in this case (large doses of vitamins A and C) was presumably based on the hope of an increase in tolerance to these substances by nonspecific means. Unfortunately, in most cases, as in this, no such general method of therapy has been found which is dependable. Nor is there any reliable method of specific desensitization against hypersensitivity to soap.

The emphasis in this inquiry on soaps used in laundering suggests that either a large dose is necessary to produce symptoms or that the fine powder of soap is more effective in producing symptoms. Careful measures for avoidance of soap contacts in the form causing irritation is the only practical advice that can be given. It would be advisable to put the soap chips gently into the water to avoid the spread of the powder into the air. The basement room in which this is done should be closed off from the rest of the house to avoid air currents through ducts, doors or windows. An inspection of the home itself might suggest the best location for introducing the soap into the water and avoiding the spread of the powder to the rest of the house. After the soap is dissolved, the spread of soap particles into the air may result

from violent agitation of the water, unless this is done in a closed room. Probably the best procedure, however, would be to send the clothes out to be washed.

TONSILLITIS IN DOGS AND HUMAN BEINGS

To the Editor:—My daughter, aged 23 months, has been ill once a month for the past few months with tonsillitis. She is ill about five days at a time and has the usual mixed throat culture. I should like to know whether my shepherd dog could be the transmitting object in this condition? Like all dogs, he is fond of licking. What is the advisability of tonsillectomy at this age and season?

M.D., Connecticut.

ANSWER.—Dogs suffer from acute sore throat and acute tonsillitis. Strains of streptococci isolated from acutely ill animals can produce sore throat experimentally in other animals. There is little evidence, however, that dogs can be responsible for acute sore throat in human beings. Pilot states that the bacterial strains producing tonsillitis, canine and human, are not alike. Hence in all probability the pet shepherd dog is not responsible for the child's illnesses. In fact, many children suffer from numerous attacks of tonsillitis in homes where there are no pets of any kind.

It is reasonable to contemplate tonsillectomy even though the child is rather young for this operation, for the attacks of sore throat are frequent and appear to be severe. The colder season is not as desirable as warmer and more settled weather, but in the last analysis the proper indications for operation become matters of judgment for each individual case.

Pilot, Isadore; Buek, C.; Davis, D. J., and Eastman, D. A.: Tonsillitis in Dogs Due to Hemolytic Streptococci, *Proc. Soc. Exper. Biol. & Med.* 34:499-502 (May) 1936.

EMERGENCY TREATMENT OF BURNS

To the Editor:—What would be the best emergency treatment to give a patient who has just sustained a severe second and third degree burn—the treatment to be given in the home or at the office while waiting for the ambulance? (The nearest hospital here is 10 miles away.)

M.D., Illinois.

ANSWER.—In the emergency treatment of burns, the most important early consideration is the relief of pain and the treatment of shock. When a person suffers an extensive burn, attempt should not be made to remove clothing. The patient should be covered with warm blankets and an effort made to conserve body heat. Sterile sheets and clean blankets should be carried in emergency kits designed for the treatment of burns. Warm fluids should be given by mouth. Pain should be relieved by adequate doses of morphine sulfate. Seriously burned patients may be immersed in a tub of warm water the temperature of which is from 95 to 100 F. This is done without removing the clothing. This procedure has the effect of supplying external heat and also of allaying pain.

When extensive burns occur on uncovered areas they may be treated as an emergency measure by the application of large wet dressings of sodium bicarbonate solution 10 per cent. Sodium bicarbonate may be kept in the emergency kit in any amounts which, when mixed with stated amounts of sterile water, will give the proper solution. For instance, 100 Gm. of sodium bicarbonate to 1 quart of sterile water makes a 10 per cent solution. The application of wet dressing of this type does not interfere with the subsequent treatment of the wound by other methods which the attending physician may prefer.

TULAREMIA AND IMMUNITY

To the Editor:—Does an attack of tularemia confer a lasting immunity? A patient had it last fall. He will not do any more hunting if there is a possibility of again contracting the disease. I find no information on the subject in textbooks.

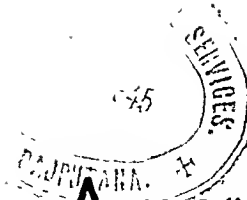

M.D., Illinois.

ANSWER.—One attack of tularemia confers permanent immunity.

SINUS PERICRANII

To the Editor:—I should like to take issue with the statement on page 236 of *The Journal* for July 19, 1941 to the effect that "sinus pericranii is seen only in conjunction with tumors of the brain." A sinus pericranii is seen only in conjunction with tumors of the brain. A sinus pericranii is a saccular cavity, often loculated, lying between the scalp and the skull usually in the neighborhood of the superior longitudinal sinus. These although I have seen one in relationship to the lateral sinus. These blood filled cavities usually communicate with the underlying sinus through an emissary vein of variable size. The contents may be fluid, in which case the cavity can be emptied by prolonged external pressure or they may be coagulated. Sinus pericranii is a congenital condition usually detected during early childhood, and is in no way related to intracranial tumors. Perhaps in this answer sinus pericranii was confused with dilatation of the extracranial venous network, which is not uncommonly seen in small children in association with intracranial hypertension.

SOME IMMEDIATE PROBLEMS FACING THE RADIOLOGIST

CHAIRMAN'S ADDRESS

RAYMOND C. BEELER, M.D.

INDIANAPOLIS

One does not have to put one's good ear to the ground to hear the rumbling sound of sudden changes and world shaking events. That these are extremely troubled times throughout the world goes without saying. It is evident that America has emphatically to assume again the role of a vigorous world power in order to remain the permanent sanctuary of certain genuinely American ideals; that, whether we like it or not, America is destined to complete the task it should have completed twenty years ago and to become, as it surely is fitted and capable of becoming, the dominant director of the nations of the world. Whether this is the actual shape of things to come for this country, time alone will tell. It hardly seems that it can be otherwise, however, as America now enters on the world scene with full mobilization of her military and her industrial resources.

What has this by-pass into the world picture to do with the subject of this paper? Primarily this: Revolutionary epochs necessitate great changes, great adjustments, great dangers and a multitude of problems. We are living in such an epoch. If we do not realize this at the outset, we can have no proper perspective of all our present day problems.

American medicine, especially in its nontechnical divisions, has gigantic problems facing it on every hand. There are economic, legal and organizational problems pertaining to national defense. American radiology as one of the very technical and complex subdivisions of American medicine shares each of the major issues facing the whole of organized medicine but, in addition to these more general problems, it has a considerable number of difficulties peculiar to its own domain. The first of these problems I wish to consider is whether or not medical radiology is to become simply a state or federal operated laboratory procedure.

The revolutionary changes in American economic and social thought over the past several years have presented American medicine with the most trying days in all its postwar history. The wide swing of the pendulum of political, legislative and even judicial thought in the United States toward socialist and collectivist doctrines has enveloped the medical profession in a legal battle the outcome of which cannot fail to have far reaching consequences for us all.

Radiology is in the most forward echelon of this conflict, placed there by the complex nature of its equip-

ment and technics and its absolute indispensability to all institutions furnishing complete medical care. It is determined not to become merely a federal or state controlled laboratory procedure. That this problem has perilously endangered our branch of the healing art arises from certain conditions and situations that have made our group especially vulnerable. We have been in the vanguard in every struggle tending to force wider and wider development of hospital insurance plans to include special medical service. The roentgenologist, the pathologist and the anesthetist have borne the brunt of the battle to date against the strenuous attempts of group hospitalization insurance plans to include radiology and other medical service in their insurance coverage.

The momentum gained by group hospitalization insurance programs, movements known as medical service plans, sickness insurance and so on, together with the gigantic inroads made by the federal government in the field of cancer diagnosis and treatment, has placed us in the greatest jeopardy. Unquestionably, the radiologist and his specialty are being used as an opening wedge through which other branches of medical practice are to be pushed for the future hospital domination over the practice of medicine. It makes little difference whether the hospital administrator, executive or superintendent is operating for a large metropolitan group hospitalization plan or is a member of the ever increasing federal bureaucracy now preparing to extend its functions into actual diagnosis and treatment of cancer; the prime objective seems to be to override any admittedly rational arguments of professional unsoundness in their plans by pouring on the public a constant din of half truths concerning the economically profitable nature of the proposed plans.

Are we going to be able to convince the public that more formidable progress against cancer can be achieved by private radiologists than under bureaucratic federal clinics? Can we convince the public that private radiologists are better qualified to prescribe the correct roentgenographic or therapeutic procedure than the most prominent hospital insurance executive? It would seem that no such task of convincing the public ought to be necessary, but a vast portion of the opposition is politically inspired, politically subsidized and politically controlled. The problem seems gigantic and overwhelming. It can be solved and our mission can be accomplished only if we close ranks, if the individual radiologist will forsake selfish considerations and join with the majority opinion of his colleagues for the duration of our emergency, prove to the public that we are not in any disagreement among ourselves and inform and educate as rapidly as possible any of our confrères who may still be unaware of what is going on and where these radical trends are taking us.

Remarkable advancement has been made lately in the field of radiology as it relates to technics developed for

rapid and economic roentgen studies of the chest, suitable for extensive surveys of large groups of persons. The great need and desirability of an accurate and economical technic for such work is recognized by every one and is not limited to the tuberculosis worker or the public health specialist. But here again a major problem is presented to us with both an economic and a technical aspect. The prime difficulty arises from the fact that because such a method for wide scale roentgenographic chest studies has been brought to the present state of development the forces who will gain most from its correct and accurate use cannot wait longer for further perfection of the technic. They clamor for wholesale chest studies while the technic they wish admits of a degree of error far greater than these zealous guardians of the public health would tolerate in any other procedure. Yet, because radiologists wish to proceed more cautiously and hence more scientifically, they are put in the disagreeable position of appearing to hold up the development and widespread application of fluorography and miniature roentgenograms (so-called 4 by 5 films). No one will claim that this method is completely perfected today. The checking of errors by conventional roentgenography is still required. The necessary preliminary accumulation of statistical data and thorough studies into the limits of the method were not allowed to be brought to a conclusion before a wholesale demand for the general use of miniature roentgenograms was made by certain groups—largely the hyphenated lay-medical agencies engaged in tuberculosis work, military induction boards and certain public health divisions.

An urgent plea is made for careful, painstaking development of this work with due regard to all its aspects, scientific accuracy, economic fairness to the individual patient in the survey group and to the radiologist performing the work and interpreting the roentgenogram and, above all, a holding off of hurried and ill considered utilization of the method simply because partially informed groups with loud voices want a mass method used on all the masses before that method is thoroughly perfected.

Another important problem which radiologists have to consider is the fact that certain manufacturers of roentgen ray equipment are willing and anxious to sell equipment to unqualified practitioners of medicine. The fact that many general practitioners have been led to believe that the installation and operation of a roentgen ray unit and the proper interpretation of films made with it is as simple a matter as ordering, installing and using an electric sterilizer is due for the most part to the avid commercialism of numerous smaller, unethical supply houses and roentgen ray manufacturers. Their number has increased greatly of late and their clientele includes as well the chiropractor, the naturopath and the electrotherapist. The outstanding feature of their work is their unique job of salesmanship. They have convinced certain physicians that, first, such a complex piece of electrical engineering requires only the knowledge needed to snap a button on and off and, second, that with the film made so easily its correct interpretation is a matter of even less effort. How they can convince their buyer that roentgen therapy requires no more than mail order knowledge I have never been able to understand.

That this is an ever growing menace is self evident to all of us assembled here. That this is a very real danger, let me cite a case with which I am familiar: Mr. A, a representative of an ethical and reliable roent-

gen ray manufacturing firm, was recently called to the office of physician X, whose apparatus had suddenly ceased to function. On going over the apparatus, Mr. A discovered that the machine showed unmistakable signs of having either been operated at extremely high milliamperage or having been used for extremely long exposures. Dr. X emphatically stated that during the three months he had possessed the machine he had used it no more than four or five times and then for but five to ten seconds for fluoroscopic work only. Closer inspection of the equipment showed that, while these examinations were being made by Dr. X, the machine had been operating at 15 to 20 milliamperes, and still closer scrutiny showed not even a piece of plate glass for protection in the fluoroscopic screen. Simply the fluorescent screen and no glass whatever. Mr. A began inquiring of Dr. X whether he had noted any changes about the skin of his face or hands. The doctor stated "Now that you mention it, I had noticed my eyes would have the most peculiar burning sensation in them a few hours after each fluoroscopic examination." Was it not a fortunate thing that the physician's apparatus failed to operate one day before he had suffered further injury?

Caveat emptor is the legal phrase in commercial law demanding that the buyer beware. For physicians foolish enough to feel that combined general practice and radiology is the field for them, there is no phrase, legal or otherwise, with which to warn them.

Aside from the possibility of the inherent physical dangers to both the general practitioner and his patient, many physicians seem totally unaware of the gigantic technical strides made in radiology since Roentgen's remarkable discovery. Radiology is no longer of such compact size or simplicity as to be considered an adjunct or sideline to any other branch of medicine. This seems too commonplace a statement to require mention, but it is amazing how many general practitioners and even certain specialists have failed to realize the many intricate subdivisions already required within the field of radiology. It is readily understood that organized radiology requires a prolonged training period for those anxious to be qualified members in it. Also that any one not taking the required course and time in preparation for the proper understanding of this science is little more than an impostor.

Last but not least of these questions before roentgenologists today is the rapid increase in size, cost and complexity of the apparatus required to perform thorough work in our field. It puts a complicated financial problem to the recently qualified young radiologist anxious to enter on the practice of his chosen specialty. The huge initial cost of equipment, high rental fee for the large office or floor space required for it, cost of expandable supplies needed, such as films and chemicals for processing them, darkroom apparatus and filing and record equipment all in addition to the salary expense of necessary clerical and technical assistants make the young radiologist's problems greater than those of any other beginning specialist. Many hospitals have taken advantage of this financial dilemma of the young radiologist to maneuver him into a position of semidependence. To be sure, not all hospitals are to be so indicated, but it has been one of the paramount means whereby certain of them have been enabled to preach the heresy of radiologic service being part and parcel of hospitalization and so through their group hospitalization insurance plans place our specialist in

the predicament discussed as problem one at the beginning of this paper.

The opportunities afforded competent radiologists to enter practice are still great. As long as medical practice in the hospitals remains medical practice and does not become hospital practice, many institutions can supply opportunities for certified radiologists. In fact, many hospital radiologic departments could double or triple the number of certified men on their present staffs with much benefit both to patients and to the visiting staff. Additional opportunities are to be found for the young radiologists throughout the smaller communities in numerous small county hospitals. No competent young radiologist need feel that this apparent financial obstacle is insurmountable, for the competent man can make his way as always.

In closing, I wish to remind you that only a few of the problems facing the members of our section have been discussed. Those of the greatest importance are being discussed by authoritative contributors to the various radiologic publications, men who are endeavoring to maintain our security now and to marshal all our available strength for the battles that lie ahead.

The important task for us all is to exert our utmost efforts, individually and collectively, to make the majority opinion of our specialty and of all organized medicine prevail, so that medical practice will continue to be run by medicine and radiologic practice by radiologists despite the tremendous upheavals occurring in the world about us.

23 East Ohio Street.

TREATMENT OF SEPTIC THROMBOPHLEBITIS OF THE CAVERNOUS SINUS

CHAIRMAN'S ADDRESS

LEROY A. SCHALL, M.D.

BOSTON

One of the most fatal complications occurring in otolaryngology is that of septic thrombophlebitis of the cavernous sinus. Previous to the advent of chemotherapy Eagleton¹ was able to report but 3 recoveries by surgical methods out of 25 cases. Browder and Myerson² had a recovery after introducing a sterile clot proximal to the infection. Grove³ surveyed the literature and came to the conclusion that septic thrombophlebitis of the cavernous sinus was practically 100 per cent fatal. Since the introduction of chemotherapy isolated case reports of recovery are beginning to appear in the literature. Barnshaw,⁴ Seydell⁵ and Pace⁶ each report a recovery following the use of sulfanilamide and Morrison and Schindler⁷ one after the use of sulfapyridine.

Read before the Section on Laryngology, Otology and Rhinology at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 5, 1941.

That there are two types of thrombosis of the cavernous sinus, the one septic and the other sterile, has been accepted clinically and proved at autopsy.⁸ My discussion will be limited to the septic type exclusively. The anatomy of the cavernous sinus has been

Fig. 1 (case 1).—Patient's appearance at the time of admission.

described by many authors⁹ and will not be reviewed again. The routes of extension of septic processes to the cavernous sinus have been well described by Eagleton.

To establish the diagnosis of septic thrombophlebitis of the cavernous sinus, Eagleton¹ proposed the following diagnostic criteria:

1. A known site of infection.
2. A blood stream infection.
3. Early signs of venous obstruction.
4. Involvement of the nerves in the sinus.
5. Neighborhood abscess of the soft parts.
6. Symptoms of complicating disease.

It has been my privilege to observe 3 cases of septic thrombophlebitis of the cavernous sinus presenting a symptomatology that fulfilled the criteria as established by Eagleton. In these 3 cases recovery occurred following the use of chemotherapeutic agents combined with heparin. That heparin is an important adjunct in treatment is demonstrated by case 2, in which the cavernous involvement developed while the patient was under treatment with chemotherapeutic agents for a nasal furunculosis.

The use of heparin in conjunction with chemotherapeutic agents was suggested to me by Dr. Champ Lyons of the Massachusetts General Hospital, and the treatment was carried out under his direction. The first 2 cases have been reported by Lyons.¹⁰ To the best of our knowledge, these cases of septic thrombophlebitis of the cavernous sinus were the first in which therapy with these agents was given.

In discussing the use of heparin, Bancroft¹¹ speculates: "For the septic processes occurring in association with otolaryngology, it would seem advisable to combine chemotherapy with heparin. The combination

Heparin is a strong organic acid, probably a mucoitin trisulfuric acid, discovered and described by Howell.¹² It was first isolated from liver, and investigations gave support to the view that it is a normal constituent of

by Schmitz and Fischer¹⁵ have rendered heparin safe to use in man.

Early experiments showed that heparin has a distinctive effect in preventing the coagulation of the blood. Howell advanced the theory that it is the inhibiting factor responsible for the fluidity of the blood, that it is not an antithrombin but that it prevents coagulation by a reaction with prothrombin, which interferes with the activation of prothrombin to thrombin. Murray¹⁶ reached the deduction that heparin also has an important effect on blood platelets in that it prevents their clumping and thereby prevents thrombosis.

Heparin has now been used in many conditions in which thrombosis is a factor—surgery of blood vessels,¹⁷ venous grafts,¹⁸ embolectomy,¹⁹ periphlebitis,¹¹ malignant endocarditis²⁰ and sudden vascular occlusion.¹¹

the blood plasma. Improved methods of extraction and purification by Howell,¹³ by Charles and Scott¹⁴ and

Heparin is administered by a constant intravenous saline drip. Usually 1,000 units of heparin, i. e., 10 mg., is added to each 100 cc. of saline solution. The saline and heparin solution is permitted to run into the patient's vein at such a rate that the clotting time of the patient's blood is maintained at the desired level.¹⁰ In these cases the clotting time of the blood was maintained at about ninety minutes as determined by the five tube method.

REPORT OF CASES

CASE 1.—A woman aged 31, seen in consultation with Dr. Vincent J. Kelley on April 5, 1940, had a nasal furuncle of five days' duration and had received small doses of sulfanilamide at home for three days.

Fig. 5.—Course of temperature, white blood cell count, clotting time, blood culture (colonies per cubic centimeter) and treatment in case 2.

With the development of the signs and symptoms of cavernous involvement, Dr. Kelley was called and the patient was admitted to the Massachusetts Eye and Ear Infirmary.

On examination the patient was irrational, the temperature was 104.3 F. and there were exophthalmos of the right eye

Fig. 6 (case 2).—Patient's appearance four weeks after admission.

and edema of the bridge of the nose and both right eyelids. There was a discharging furuncle of the right naris, and the frontal veins were palpable.

In consultation, Dr. Lyons suggested the use of heparin in conjunction with chemotherapy, and the treatment was carried

out under his direction. The treatment and course of the disease may be rapidly reviewed by the following clinical notes:

First hospital day: Heparin and sulfapyridine started.

Fourth hospital day: Sulfathiazole substituted for sulfapyridine, as the blood culture showed staphylococci.

Eleventh hospital day: Pulmonary infarct.

Seventeenth hospital day: Heparin stopped after a total dose of 225,000 units.

Twentieth hospital day: Sulfathiazole stopped.

Thirty-fourth hospital day: Clinical signs of meningitis confirmed by lumbar puncture. Sulfapyridine started.

Forty-ninth hospital day: Meningitis still present. Sulfathiazole substituted for sulfapyridine.

Fifty-seventh hospital day: Afebrile and symptomatically improved.

Seventy-seventh hospital day: Discharged home; taking sulfathiazole.

At the time of discharge there was a partial paralysis of the third nerve and complete paralysis of the fourth nerve on the

Fig. 7 (case 3).—Patient's appearance at the time of admission.

right. Chemotherapy was continued for a total period of four months, at the end of which time the spinal fluid protein had returned to normal.

On May 15, 1941 the patient was admitted to the psychiatric ward of the Massachusetts General Hospital suffering from a paranoid-like attack, the exact nature of which has not as yet been determined.

CASE 2.—A man aged 41, an engineer, entered the Massachusetts Eye and Ear Infirmary May 14, 1940 with the diagnosis of acute frontal sinusitis of one week's duration. Physical examination revealed a nasal furunculosis, and the diagnosis of acute sinusitis was not supported. On entry he was started on sulfapyridine therapy, but by the fourth hospital day exophthalmos of the right eye and edema of the eyelids and the bridge of the nose developed, with palpable frontal veins. Heparin was started on the fourth day and stopped on the nineteenth after a total dose of 580,000 units. During the course of the disease involvement of the sixth and the first division of the fifth cranial nerve developed. Sulfathiazole was substituted for sulfapyridine on the eleventh hospital day because blood cultures showed staphylococci.

Sulfathiazole was given for three months, at the end of which time the spinal fluid protein was normal. The patient still has a residual hyperesthesia of the left frontal region.

CASE 3.—A boy aged 9 years, referred to me on Jan. 7, 1941 by Dr. Charles W. Geddes with a diagnosis of cavernous sinus

Fig. 8.—Course of temperature, white blood cell count, clotting time, blood cultures (colonies per cubic centimeter) and treatment in case 3.

thrombosis, was awakened from sleep three days before entry by a pain in his nose with some swelling of the face. His father noticed a small elevated area inside the left nostril. Under flaxseed poultices the swelling became worse and a furuncle in the nose broke and discharged.

Fig. 9 (case 3).—Patient's appearance four weeks after admission

On admission to the hospital there were exophthalmos and edema of the right eyelid and the bridge of the nose. The temperature was 102 F., and there was headache, with stiffness of the neck and a slight Babinski reflex on the right side.

The patient was drowsy, and blood cultures were positive for staphylococci. The patient was placed under the care of Dr. Lyons, and the hospital record can be summarized as follows:

First hospital day: Heparin 20,000 units given with sulfathiazole. Slight bleeding from nose.

Second hospital day: Sixth nerve paralysis.

Third hospital day: Involvement of first and second division of fifth nerve.

Ninth hospital day: Heparin stopped.

Tenth hospital day: Lumbar puncture done. Fluid crystal clear. Initial pressure 125.

Eighteenth hospital day: Patient up in chair.

Twenty-fourth hospital day: Sulfathiazole stopped.

Twenty-eighth hospital day: Temperature rose to 100.8 F. Pain on coughing; lumbar puncture, no increase in pressure—clear fluid, 1 cell.

Twenty-ninth hospital day: Sulfathiazole started again; temperature 102 F.

Thirty-fourth hospital day: Patient symptom free

Thirty-ninth hospital day: Patient discharged home—sulfathiazole ½ grain (0.03 Gm.) twice a day for six to eight weeks.

Total amount given: 130,000 units of heparin and 108 Gm. of sulfathiazole.

COMMENT

Three consecutive cases that fulfilled the diagnostic criteria of Eagleton of septic thrombophlebitis of the cavernous sinus of the anterior type have ended in recovery after treatment by the combination of chemotherapy and heparin.

Lyons¹⁰ states: "There is reason to believe that staphylococcal bacteremia usually arises from foci of septic thrombophlebitis in and around areas of supuration. Such a conception indicates that the attack upon any staphylococcal bacteremia should attempt to prevent the extension of septic thrombi as well as to destroy the bacteria."

It is contended not that heparin has any influence on a thrombus that has already formed but that, by increasing the fluidity of the blood, it may prevent the extension of that thrombus. Sterilization of the blood and the thrombus converts a septic process into an aseptic one, so that the combination of these drugs seems to be indicated.

CONCLUSIONS

1. Three consecutive patients with bacteremic staphylococcal thrombophlebitis of the cavernous sinus of the anterior type have been successfully treated by a combination of chemotherapy and heparin.

2. Sulfathiazole, given in doses sufficient to maintain a blood level of 5 mg. per hundred cubic centimeters and continued for a long period after administration of the heparin has been discontinued, has been the chemotherapeutic agent of choice. Experience with sulfadiazine indicates that this may prove to be the present drug of choice.

Fuel Values.—Nutrition laboratories have, as the result of many experiments, determined the average loss of fuel value in the body from these sources and, after deducting for such losses, give the following figures as the "physiological" fuel value of the three foodstuffs: 1 gram of pure carbohydrate, 4 calories; 1 gram of pure fat, 9 calories; 1 gram of pure protein, 4 calories. It is important to remember that the fuel value of fat is 2¼ times that of carbohydrate or protein, and hence foods rich in fat are especially high in fuel value.—Bogert, L. Jean, and Porter, Mame T.: *Dietetics Simplified*, New York, Macmillan Company, 1940.

CAISSON DISEASE

A STUDY BASED ON THREE HUNDRED CASES
OBSERVED AT THE QUEENS-MIDTOWN
TUNNEL PROJECT, 1938

I. J. THORNE, M.D.
NEW YORK

Caisson disease is an industrial hazard encountered in the building of bridges, tunnels and skyscrapers where compressed air is employed. In the past this malady has caused permanent disability and death in many instances. Certain principles of prophylaxis and new concepts of treatment are here presented aiming to reduce this industrial hazard.

THE CAUSATION OF CAISSON DISEASE

Caisson disease is caused by nitrogen gas, a physical agent. Emboli are produced by the formation of nitrogen gas bubbles in the tissues and blood stream which interfere with normal life processes.

A homogeneous mixture of gases in the atmosphere covers the earth to a height of approximately $4\frac{1}{2}$ miles. The atmospheric pressure is the weight of these gases on the earth's surface and is expressed in pounds per square inch. Although atmospheric pressure varies slightly, it is approximately 15 pounds per square inch.

The interchange of gases in the lungs and blood of a person who is in a compressed air atmosphere obeys the law of physics governing the solution of a gas in a liquid.¹ The quantity of nitrogen and oxygen dissolved by the blood varies directly as the pressure. The increased amount of oxygen absorbed is readily metabolized because it is an active gas chemically. This is not true of nitrogen, which is inert and is not utilized by the body.²

The increased amount of nitrogen dissolved in the blood is absorbed by the various tissues of the body according to their ability to hold nitrogen in solution. Fat and fatty tissues will dissolve much more nitrogen because nitrogen is five times more soluble in fat than in other tissues and body fluids.³ The amount of tissue saturation with nitrogen depends on the amount of air pressure and the length of time the body is exposed to this pressure.

When a person who has worked in compressed air is exposed immediately to normal atmospheric pressure, a phenomenon occurs similar to the sudden opening of a bottle of charged water. For example, bubbles of carbon dioxide will evolve from the charged water and will continue until equilibrium of partial pressures of carbon dioxide in the atmosphere and in the liquid is obtained. A similar phenomenon occurs in the blood and the body tissues under sudden release of pressure. The dissolved nitrogen gas evolves in the form of bubbles, producing blocking of the circulation and tearing of tissues with resultant symptoms of caisson disease. Bert's experiments add further evidence for the support of the nitrogen gas emboli theory as the cause of this disease.⁴

PATHOLOGY

Accumulation of evidence from postmortem examinations further supported the gas emboli theory as the cause of caisson disease.⁵ Fatal cases grouped themselves into a rapidly fatal group and a delayed fatal group. In the rapidly fatal group, death is caused by nitrogen emboli to the vital centers of the brain, the coronary vessels and the pulmonary arteries.

In the delayed death groups, death is caused by secondary complications following neurologic manifestations of the disease. After long standing paralysis of the lower extremities, bedsores, sepsis, anemia, pneumonia and exhaustion usually develop. The significant pathologic changes in the delayed death group are found in the spinal cord. The lumbar and thoracic regions of the cord show areas of necrosis and softening with degeneration and destruction of ascending and descending fibers.

SIGNS AND SYMPTOMS

Onset of Symptoms.—The onset of symptoms of the disease is relatively rapid. Of the 300 cases observed 60 per cent occurred during the first hour, 35 per cent during the second hour and 3 per cent during the third hour. Six cases occurred after twelve hours, amounting to 2 per cent of the total.

Presenting Symptoms.—Pain (the "bends"): The presenting symptom of the disease was pain. The cases observed formed groups clinically as follows: pain generalized, pain localized and pain with prostration and collapse. The pain of compressed air disease may vary in intensity, depending on the site of bubble formation and the amount of gas evolved in the tissues. The pain may thus be mild and transient or severe and excruciating. The occurrence of pain in various parts of the body according to incidence is as follows: legs 50 cases, unilateral or bilateral, occurring generally about the knees and ankles; arms 60 cases, unilateral and bilateral, involving several joints. It may radiate or follow the course of a peripheral nerve. Abdominal bends may be of such severity that shock, collapse and prostration occur, forming the next clinical group. Here pain in the abdomen is outstanding. It is often accompanied by signs of circulatory collapse because of the great amount of gas in the abdominal vessels mechanically impeding the circulation. The appearance of mottling and blotching with subcutaneous hemorrhages is further evidence denoting large amounts of free gas in the circulation. These are prodromal signs of coma and collapse, which should be carefully watched for. To the compressed air worker these symptoms are known as the "bends." The reason for this vernacular expression is obvious. The pain is of such severity as to make the afflicted one bend over to obtain relief. The pain is caused by the presence of bubbles of nitrogen gas in the tissues and the plugging of small arteries by nitrogen gas emboli. The lodging of nitrogen gas emboli in the gastrointestinal and mesenteric vessels is undoubtedly the cause of abdominal bends. Likewise, when bubbles of gas form in unyielding structures and tissues of the body such as ligaments, fascia, connective tissue, periosteum, synovial membranes, muscle spindles, joint capsules, skin and sweat glands, pain is the result. The greater the amount of gas, the greater will be the stretching of the unyielding tissues with the resultant increase in pain. Most compressed air workers suffer on decompression

1. Travers, M. W.: *The Experimental Study of Gases*, New York, Macmillan Company, 1901, chapter 9.

2. The quantity of a gas dissolved by a liquid increases directly as the pressure (Henry, 1803). The quantity of a gas dissolved by a liquid from a mixture of gases depends on the partial pressure of that particular gas (Dalton, 1807).²

with mild fleeting pains in the various parts of the body which should be differentiated from true caisson disease.

Vertigo (the "staggers"): Next in the order of incidence are the cases in which symptoms resembling Ménière's syndrome are outstanding. The symptoms are dizziness or vertigo, staggering or loss of equilibrium, nausea or vomiting, abnormal ocular movements (nystagmus) and tinnitus, or ringing in the ears. Of the 30 cases observed at the Queens-Midtown Tunnel in 1938, there was vertigo in 6, vomiting and vertigo in 6, vertigo, vomiting, staggering and nystagmus in 10 and vertigo, nausea and tinnitus in 8. These symptoms are evidently caused by the evolution of nitrogen bubbles in the internal ear, labyrinth, cochlea and semicircular canals. To the compressed air worker this syndrome is known as the "staggers." A worker suffering from the "staggers" resembles a man who has indulged in alcoholic excess. Unless the worker's identifying badge is seen, the man is believed to be an alcoholic addict and is treated as such. This is one important reason why compressed air workers should wear their identifying badge where it can be readily seen and detected.

Air Hunger (the "chokes"): Dyspnea is characteristic of this group. These patients appear acutely ill and present a condition which is alarming. However, they yield readily to treatment, provided it is given immediately. Compressed air workers suffering from this symptom complex resemble an asthmatic patient. Physical examination of the chest reveals bilateral medium and fine moist and musical rales. These patients also resemble persons with heart disease suffering with sudden left ventricular failure and transitory pulmonary edema. This clinical picture is familiar to the compressed air worker and is known as the "chokes." Fifteen cases of the "chokes" were observed at the Queens-Midtown Tunnel. The symptoms are caused by varying amounts of nitrogen emboli in the pulmonary arteries.

Cutaneous Manifestations (the "itch"): The various cutaneous manifestations noted in the cases studied were pruritus (the "itch"), erythema and mottling and blotching. There were 20 cases presenting cutaneous manifestation of the disease: 6 presented only pruritus, 5 a combination of pruritus, erythema and blotching of the skin. Erythema and mottling of the skin were present in 6 cases. The intense itching is caused by nitrogen bubbles in the sweat glands of the skin. The erythema and purplish mottling of the skin denote stasis of blood in the cutaneous vessels as a result of nitrogen emboli in the skin capillaries. Cutaneous signs are usually early signs of compressed air illness. They signify possible ensuing symptoms of much greater severity. Therefore persons presenting cutaneous manifestations should be carefully observed for severer symptoms. Of 6 cases in which mottling and blotching of the skin were present, the "staggers" developed in 2 and the "chokes" in 4.

Neurologic Manifestations: This group of cases is important from the point of view of its disabling character and the possibility of permanent damage to the central nervous system. Patients with central nervous system symptoms who are not treated promptly are apt to develop permanent disability.

The nerve cells and tissues of the central nervous system are vulnerable to ischemia and pressure from nitrogen bubbles with consequent pressure necrosis.

Thus the reasons for permanent damage can readily be seen. Nitrogen bubble formation can occur in any part of the brain or spinal cord. Nitrogen emboli can form locally in the blood vessels or be carried to the central nervous system by the blood stream from other parts of the body. The central nervous system symptoms produced by compressed air disease can simulate those caused by any other disease or injury of the central nervous system. Complete unconsciousness and collapse to numbness and tingling of an extremity can be expected.⁶

Paralysis of the bladder and bowels is common in spinal cord cases. The majority of afflicted persons recover with treatment, while some remain with permanent weakness of the lower limbs. In some instances the patient dies after a lingering illness, death being caused by secondary complications such as cystitis, pyelonephritis, bedsores, pneumonia, exhaustion and anemia. Twenty-five cases of central nervous system symptoms occurred at the Queens-Midtown Tunnel: with brain involvement, hemiplegia 3 cases, monoplegia 2 cases, internal strabismus 2 cases, nystagmus 2 cases, diplopia 2 cases; with spinal cord involvement, sensory, numbness and tingling of both legs 5 cases, motor, paresis of both legs 4 cases, paralysis of both legs 2 cases, sensory and motor disturbance, numbness and tingling and paresis 3 cases. Urinary and bowel incontinence are present in all spinal cord cases in addition to the symptoms mentioned. Recovery was complete with treatment except in 1 case of paralysis of both legs. Urinary and bowel control were regained but weakness of both limbs remained.

DIAGNOSIS AND DIFFERENTIAL DIAGNOSIS

The diagnosis of caisson disease is not difficult. Although the symptoms are varied and depend on the parts of the body involved, there should be no doubt as to the diagnosis provided the patient is conscious and can give a history of exposure to compressed air during the preceding twelve hours. The identification badge that the compressed air worker wears conclusively confirms the diagnosis. It is conceivable that the identifying badge might not be worn and the worker might be in coma and unable to give a history. Furthermore, compressed air workers are susceptible to other injury or illness in addition to caisson disease. In such instances the diagnosis becomes more difficult and a careful differential is always necessary. A severe case of abdominal bends can simulate an acute surgical condition of the abdomen and conversely an acute surgical condition of the abdomen can simulate abdominal bends. True caisson disease must be differentiated from mild cases of myalgia, arthralgia and neuralgia. Aside from caisson disease, 135 cases of mild pain in the extremities were observed. Most of these cases responded to physical therapy and medication. The pains were located chiefly in the joints and extremities. They were described as vague aches and pains in the thighs, legs, arms, knees, ankles, elbows, wrists, shoulders and along the course of the peripheral nerves. The pains

were transitory and not severe enough to incapacitate the patient but were aggravated with change in temperature.

Physical examination revealed three clinical groups as follows: pains limited to muscles, myalgias; pains limited to joints, arthralgias; pains limited to the course of a peripheral nerve, neuralgias. Combinations of the three groups were also seen. It is believed that these cases are the result of the decided change in temperature on compression and decompression, the unusually damp atmosphere of the tunnel environment and the poor local tissue circulation resulting from fatigue following strenuous physical effort.

COMPLICATIONS

The complications of caisson disease are limited to the bones and joints. The symptoms of onset are insidious and are delayed from six months to a year or more following repeated attacks of the disease. A case of bone necrosis was reported in 1888 by Twynam.⁷ Cases of chronic arthritis were reported by Bornstein and Plate⁸ in 1911 and 1912 following repeated attacks of the disease. Bassoe⁹ in 1913 reported several cases of arthritis deformans. Christ¹⁰ in 1934 reported joint lesions. It is possible that nitrogen emboli in end arteries of nutrient vessels to bones might cause necrosis and degenerative changes in bone. Four cases of aseptic bone necrosis attributed to caisson disease were reported by Kahlstrom, Burton and Phemister¹¹ in 1939.

PROGNOSIS

The mortality of caisson disease has dropped to an exceedingly low figure at the present time because of the efficiency of the recompression treatment. Prior to the use of the medical lock the mortality rate was high. Blick¹² in 1909 reported 30 per cent mortality among pearl divers, 60 out of 200 patients dying before medical aid could be given. Jaminet¹³ in the St. Louis bridge construction reported 119 cases with permanent paralysis in 52 and death in 14, representing a 14 per cent mortality. Dominguez¹⁴ reported 106 cases of serious paralysis with 14.9 per cent mortality. During the building of the Brooklyn bridges the mortality was 3 per cent. During the work on the Hudson River tunnels the advantages of recompression were amply shown on the installation of a medical lock. After the medical lock was employed the mortality rate dropped from 25 per cent to 1 per cent. The mortality rate in building the Pennsylvania Railroad East River tunnels was 2 per cent. In 300 cases observed during the building of the Queens-Midtown Tunnel there was no mortality from this disease. In cases of sudden collapse and unconsciousness the prognosis is graver than in cases presenting only pain in the extremities. Those in which paralysis is present are difficult to cure, and advice as to the outcome should be guarded.

PROPHYLAXIS AND PREVENTION

In addition to nitrogen embolus formation, certain secondary conditions predispose an individual toward caisson disease. They are age, systemic disease, obesity, alcoholism and fatigue.

It is the consensus that the ideal age for compressed air workers is between 20 and 40 years, since during these years the cardiovascular system is at its peak of greatest efficiency and best able to withstand the hardship of increased air pressure. Diseases of the heart, lungs and kidneys and peripheral vascular diseases are grounds for rejection. These conditions should be carefully ruled out during the first examination. Obese men are bad risks because of the great solubility of nitrogen in fat. Men who are known to be habitual drinkers are poor risks because of the effect of alcohol on the circulation and should be rejected.

A man who is acutely ill should not be admitted to compressed air until he has recuperated. Acute infection of the upper respiratory passages should temporarily disqualify a man for employment, because the infection usually involves the eustachian tubes and ostia of the sinuses, causing adhesions of the walls and consequent closure. When one is entering the compression chamber the ear drum is stretched, causing severe pain. This is known as "ear block." Infection of the mucous membrane of the ostia of the sinuses causes acute edema. Valvelike action occurs, allowing air to enter the sinus; but its escape is prevented. Air under pressure becomes trapped in the sinus, causing severe pain. This is known as "sinus block." Acute infection of the sinus may follow from organisms driven into the sinus by the compressed air, requiring surgical intervention. Failure of the eustachian tubes to open to equalize the pressure on either side of the tympanic membrane will result in rupture of the tympanum with consequent infection of the middle ear.¹⁵ Fatigue predisposes to emboli and the "bends" because of its effect on the circulation, causing slowing of the elimination of nitrogen gas.

There is no immunity to caisson disease. Consequently the most important step in the prophylaxis is the physical examination with special emphasis on the heart, lungs, circulatory system, circulatory efficiency and cardiac reserve. The importance of age, weight and habits should not be overlooked.

Approximately 20 per cent of the men examined at the East River tunnels were rejected. Men who show symptoms of caisson disease after one or two trial test shifts would be rejected. Many of the men suffer from repeated mild attacks of pain and itching of the skin, but there is no need for rejection on such mild symptoms.

The ultimate prevention of the disease depends on the proper elimination of nitrogen from the tissues during decompression. There is only one route by which the nitrogen in the body tissues and blood can be eliminated, and that is through the lungs by the circulation. Any condition affecting the efficiency of the circulation is likely to affect the efficiency of the elimination of the nitrogen gas from the tissues. During the decompression stage the value of exercise in stimulating the circulation cannot be overemphasized. The extreme importance of slow decompression should always be borne in mind. The working time under

pressure should always be held within safe limits with adequate rest periods between shifts. This is important, because the amount of nitrogen absorbed depends to a large extent on this time factor. The inhalation of oxygen and oxygen-helium mixtures during the decompression period to hasten the nitrogen release from the body is a valuable prophylactic measure. Sudden changes in temperature should be avoided. Therefore the temperature of all air locks should be controlled by suitable heating apparatus to keep the temperature as constant as possible.

TREATMENT

The essential treatment of caisson disease is the return of the patient to the compressed air. In previous years, men who were seized with an attack voluntarily returned to the compression chamber for the relief of their symptoms. Today this treatment is given in a compression chamber known as a "medical air lock."¹⁶

Only those who have witnessed the treatment of a case of compressed air illness can realize the efficacy of recompression. Recompression should be started as soon after the onset of symptoms as possible, because the sooner the bubbles of nitrogen are redissolved the sooner will the circulation be established and pain relieved. The possibility of permanent damage to vital structures such as the brain and spinal cord will be materially reduced by immediate recompression. It has been noted that if treatment is delayed following the onset of symptoms a higher pressure is necessary to give relief. Long delay in recompression may result in permanent injury to the cord because of anemia as a result of the circulation being blocked by nitrogen emboli. It is true that recovery will occur in certain mild cases without recompression, but there are no criteria by which we can determine which cases suddenly become serious. It is most advisable therefore to treat all definitely diagnosed cases of the disease by recompression immediately.

Of 300 patients treated at the Queens-Midtown Tunnel airlock, 85 per cent were completely relieved, 12 per cent were partially relieved and 3 per cent had no relief. Experience has established that symptoms in most cases are relieved by recompression to a pressure equal to that to which the worker was exposed. Occasionally it is necessary to go 5, 10 or 15 pounds higher before complete relief is obtained.¹⁷

The consensus favors waiting twenty to thirty minutes before starting the decompression process. Observations have proved that this waiting period has given the best result. In many instances symptoms recurred if decompression was started immediately with no waiting period, requiring another recompression. To avoid repeated recompressions, it was found advisable to introduce this waiting period before starting the decompression process. Despite the waiting period, however, symptoms are apt to recur requiring one or more additional recompressions.

It was noted that if the men were made to exercise the affected limb during the decompression process it aided materially in obtaining a permanent relief. The inhalation of pure oxygen and oxygen-helium mixtures during decompression has given encouraging results

in many instances. These gases hasten the elimination of dissolved nitrogen from the blood and hence decrease the tendency toward the disease.¹⁸ The importance of stimulating drugs as adjuncts in treatment should not be minimized. Strychnine, epinephrine and caffeine are valuable circulatory stimulants and one should not hesitate to use these drugs in cases of circulatory collapse. In cases of respiratory failure, artificial methods should be instituted. Physical therapy and general nursing care should be given whenever necessary.

SUMMARY

1. Three hundred cases of caisson disease occurred without mortality during the building of the New York Queens Midtown Tunnel in 1938.

2. Serious disability in these cases was also practically nil. This remarkable result may be attributed to:

The selection of workers between the ages of 20 and 40 years, free from acute or chronic disease and with freedom from pulmonary, cardiovascular, renal, peripheral vascular or gastrointestinal diseases and obesity.

Prompt recompression of all subjects exhibiting the slightest symptoms of caisson disease, thereby minimizing neurologic phases of the disease, which ordinarily when neglected prove most disabling or fatal.

The prophylactic inhalation of oxygen and oxygen-helium mixtures in the decompression stage, thus hastening nitrogen release.

The rigid regulation of the duration of the working shifts and rest period between shifts according to prescribed pressure-time codes.

20 West Seventy-Second Street.

RADIATION PROTECTION IN FORTY-FIVE HOSPITALS

LEONARD A. SCHEELE, M.D.

AND

DEAN B. COWIE

Passed Assistant Surgeon and Research Fellow, respectively, National Cancer Institute, National Institute of Health, United States Public Health Service

BETHESDA, MD.

The increasing use of radiation in medicine, industry and research demands increased knowledge of radiation effects and protection methods. The authors visited forty-five hospitals of all types, ranging in size from forty-four to over three thousand beds (thirty-two have more than two hundred beds) and studied storage and handling of radium, calibration and shielding of roentgen therapy equipment and techniques of use and shielding of roentgenographic and fluoroscopic units.

Ionization chambers ranging in sensitivity from 0.25 roentgen to 100 roentgens full scale were used in making measurements. Estimates of average exposures were calculated from ionization measurements made during typical operations such as preparation of radium applicators and roentgenoscopic and roentgenographic procedures, multiplied by the average daily time spent performing such activities. Adequacy of equipment and practices were judged in most instances on the basis of recommendations for protection which have been pub-

16. The first recompression chamber in the United States was installed during the building of the New York Hudson tunnels under the North River in 1894. This was known as a "medical lock" and because of its efficiency it was made essential to the equipment of all compressed air work.

lished by various writers¹ and those in the National Bureau of Standards handbooks on roentgen ray² and radium protection.³ The authors used the 0.1 roentgen dose which is published in these handbooks as the safe daily tolerance dose.

RADIUM

Relationships between amounts of radium, distance from the nearest person to the radium and time spent at such distance were studied, and it was found that lead equivalents of storage blocks were such that overexposure occurred in sixteen of the forty-five hospitals and was borderline in thirteen. Storage in safes in administration offices was a frequent cause of excessive exposure of nontechnical personnel. Radium units, especially those in assembled applicators, were found outside the storage blocks in more than one fourth of the hospitals.

Fourteen institutions had no L blocks, and ten had blocks less than 2 inches (5 cm.) in thickness. Four of these were less than $\frac{1}{4}$ inch (0.64 cm.) thick. Radium was often assembled in more than one place in the hospital, yet only one L block and set of assembly instruments had been provided.

Instruments for assembly were excellent in twenty-four institutions. In the remainder, either no special instruments had been provided or those at hand were inadequate. Frequent use of fingers was noted during manipulation. Lack of education and supervision of subordinate personnel often contributed to overexposure. Table 1 shows the exposures found during the assembly of single applicators for intra-uterine use.

Hands, paper boxes, glass jars and inadequate lead boxes were used as carriers in the majority of the institutions.

ROENTGEN DIAGNOSIS

Roentgen departments had excellent lead-lined control rooms in twenty-three of the forty-five hospitals. Thirteen had no protection for the operator except that around the tube, and this usually was incomplete or insufficient. The remainder had only partial lead protection.

Many technicians held the majority of infants and patients speaking only a foreign language who came for roentgenograms, and one received exposures on the hands as high as 35 roentgens while holding a single patient. Other daily exposures ranging from 1 to 5 roentgens were observed.

Open lead glass bowls were found to be in frequent use. The majority of technicians working with them did not have the benefit of adequate shielding at the control panel and received daily doses in excess of 0.1 roentgen. Four instances were noted in which the unshielded operator at the control panel was in the direct beam of the tube, and one of these received 0.2 roentgen a day doing only sinus series.

In several instances the holding of films or patients during portable roentgenography resulted in overexposure. In one case the hands received 0.42 roentgen and the body 0.14 roentgen during the making of two exposures.

The greatest repeated overexposures were found during fluoroscopy. The worker depends on inherent protection in the equipment and other protective devices such as lead-rubber aprons and gloves to shield him from overexposure, because it is impossible to do fluoroscopy at a distance in a shielded control room.

The lead glass in the fluoroscopic screen provided adequate shielding in all institutions; however, it was found that the shutters of thirty of the units did not restrict the direct beam to the protected screen area. There was considerable overlapping when the shutters were wide open with the screen 40 cm. above the table top. Since average intensities at the surface of the table were approximately 13 roentgens a minute without a patient at 75 kilovolts and 5 milliamperes, it was possible for the examiner to receive large doses on his hands if he worked with the shutter wide open and no protective gloves. A careful check revealed that most radiologists were unaware of the fact that often they opened widely one or the other pair of leaves of the shutter at intervals during each examination, especially during examinations of chests and bones. Hand-held portable screens were found to be great offenders in permitting overexposure.

TABLE 1.—Body and Finger Exposures in Selected Cases During Assembly of a Single Radium Tandem for Intra-Uterine Insertion

Case	Applicator Material	Radium		L Block Thickness, In.	For-ceps Length, In.	Elapsed Time, Min.	Exposure in Roentgens	
		In Applicator, Mg.	Other on Table, Mg.				Body	Fingers
A	Rubber	85	275*	2	10	31	0.02	25.0
B	Silver	90	10	$\frac{3}{4}$	8	12	0.04	0.4
C	Rubber	75	None	None	10	10	0.05	1.5
D	Rubber	75	125*	None	4	20	0.05	30.0

* In open lead box.

Average exposures to the hands of the examiner during fluoroscopy were found to be such that doses could not be held under 0.1 roentgen a day unless gloves with 0.5 mm. of lead equivalent were worn as a routine. In spite of this, one fourth of the radiologic departments possessed no lead rubber gloves, or such gloves were never used. The practice of wearing pigskin or canvas gloves, offering inadequate protection during typical fluoroscopic examinations, was found to be frequent. In the institutions in which gloves were used, many of the gloves were found to be old and to have missing lead protection on the sides of the fingers or other local defects, thus failing to provide efficient protection.

Fluoroscopic rooms were checked at various points for stray radiation with a hand screen, and it was found that there was sufficient scattering in twenty-seven such rooms to permit resolution of the bones of the fingers 10 feet from the table with the units operating at 75 kilovolts and 5 milliamperes. Aprons were checked for effectiveness in reducing the exposure hazard in these hospitals, and extreme variations were found in the protective value of the aprons owing to sizable differences in their lead content. Aprons with 0.5 mm. lead equivalents placed on the table top in the direct beam reduce the intensity at the screen to such a level that no fluorescence can be seen on it. Many aprons were found to have lead equivalents well under 0.5 mm., and in one case eight thicknesses of apron in the direct beam permitted sufficient fluorescence to occur to enable one to examine bones of the hand. Aprons were worn by technicians in the fluoroscopic examination rooms of

only seven hospitals, although scattering was of such intensity in many of the rooms as to permit them to receive more than 0.1 roentgen a day. It is noteworthy that the age of the equipment was not found to be a factor in the levels of overexposure discovered.

ROENTGEN THERAPY

Thirty-nine of the forty-five hospitals visited had equipment for high voltage roentgen therapy. Only four in this group had inadequate shielding, although the technic used in a few of the others caused occasional overexposure. Shifting of patients with the tube in operation and failure to close the lead protective door were the principal faulty technics noted.

Calibrations were checked in thirty-seven of the institutions. Table 2 shows the errors found with reference to frequency of calibration. One fourth of the calibrations in use had errors of more than 10 per cent. Most of the errors were such that fewer roentgens were delivered in a given period of time than the calibration in use indicated. Of the twenty hospitals calibrating oftener than once a year, only three had

differences, and none of these exceeded 15 per cent. Six of the remaining seventeen institutions in which calibrations were checked once a year or less often showed errors, the greatest of which was 50 per cent.

Table 3 shows the errors with reference to the person calibrating. In the twenty-seven hospitals in which registered physicists, radiologists or staff physicists made the measurements, only one of the calibrations in use was found to be in error. Eight of the ten institutions in which technicians and others calibrated had errors of more than 10 per cent.

The principal reasons for the differences found were as follows: (1) Calibrations were too infrequent, (2) persons calibrating were not thoroughly familiar with the proper methods of doing such work, (3) local calibration equipment was not standardized and (4) stop watches, timers and integrating devices gave erroneous readings. The first two were the principal causes of variations.

INJURY

Extensive study of injuries of workers was not feasible in this survey owing to time limitations; however, a few observations were made.

Blood counts were routine procedures in only nine institutions. Several instances in which total leukocyte

counts fell below 5,000 and total red counts and hemoglobin content were reduced were noted, but the methods of performing counts in most cases were not objective enough to permit any real significance to be attached to them.

Cutaneous effects varying from atrophy to the formation of epithelioma were noted in twelve radiologists (20 per cent of the radiologists seen) and five technicians. The total population observed was approximately two hundred and twenty-five, of whom the majority were technicians whose employment had been relatively brief. Those with injuries had had exposures to radiation varying from ten months to twenty-five years, and the majority had been exposed more than fourteen years.

No observations on genetic injuries could be made from data available during this survey.

SUMMARY

A study of protection in forty-five hospitals has shown that there are so many points in mechanics and practices which must be carefully controlled if overexposure is to be prevented that no hospital was able to eliminate all possibility of excessive exposure. In general, hospitals tended to have good protection in most particulars or inadequate protection in most particulars.

It was found that careful compliance with the recommendations in the handbooks on radium and roentgen ray protection enabled even the busiest workers to receive daily doses in the order of 0.02 roentgen or less. However, equipment and practices, as they were found, caused a large number of the workers to receive more exposure than the recommended 0.1 roentgen a day.

In the hospitals visited, too little attention was paid to adequate education and supervision of technical workers handling radium and x-ray equipment. Many workers, other than radiologists, who used x-ray equipment and radium had little knowledge of radiation physics.

The need for adequate lead protection in storage and L blocks for radium and careful choice of site for such storage and assembly were often ignored.

Obsolete equipment and failure to provide or use lead protective barriers during roentgenography permitted many cases of overexposure to occur. Excessive exposure was found to result from the commonly observed practice of holding patients during roentgenography.

Both radiologists and technicians received considerably more radiation during fluoroscopy than they were aware of. These exposures were the most excessive noted in the survey.

It was found that less inherent protection had been built into most equipment and protective devices than radiologists generally realized. Few persons had made adequate measurements to reveal the adequacy of protection in their departments.

In one fourth of the thirty-seven hospitals in which calibrations were checked, errors exceeded 10 per cent. Radiologists and physicists were found to be the most competent groups to do calibrations. Calibrations were too frequent in many hospitals to permit accuracy in the calculation of doses given to patients.

The impression was gained by us that too little attention has been paid to protection with reference to both equipment and practices in most of the hospitals visited. The casual finding of twelve injuries among sixty

radiologists is evidence of the need for further study of tolerance doses, the problems of shielding of equipment, and operating technics.

ABSTRACT OF DISCUSSION

EDITH QUIMBY, M.A., New York: Many like to think that radiologists are so conscious of the hazards of their profession that they all make sure of adequate protection. This paper should open our eyes. All the failures reported by Drs. Scheele and Covie have been in departments under the supervision of qualified radiologists. Some of the most flagrant examples of carelessness were made by technicians whose chiefs disclaimed knowledge of what had been occurring. This is a serious indictment—but how many of you know all of your technicians' short cuts? Do you know whether your radiographic tube can ever point at an open door? Do you know how many times your technicians are endangered by holding patients whose cooperation they cannot secure? How many of you have made sure that your lead rubber gloves and aprons have been tested, and how many of you wear them when they have been tested? How many of you know the equivalent of protection in your fluoroscopes? And how many of you know how much scattered radiation they are getting, even though you yourself may be safe? How many of you know what procedure your radium technicians go through in making up applicators, whether they fumble around with the forceps and then pick up the tubes with their fingers and jam them into place? How many of you know how long the radium applicators lie around in occupied rooms before or after they are used? There should be no need for reviewing the protection requirements; they have been published in the radiologic journals and in the bulletins of the Bureau of Standards. But it is not always easy to see just how a particular installation or procedure fits into standard recommendations. For this reason your radiologic organizations, through their standardization committees, maintain a list of registered radiologic physicists. These men and women have all passed a comprehensive examination covering calibration and protection methods, and they are available for consultation on these matters. They will go over existing installations, make complete surveys and give you their recommendations or they will go over plans and offer advice before a new installation is made. In the first case they may pick up difficulties before you get into trouble. In the second they can insure satisfactory protection, and at the same time they may be able to save you money by knowing where maximum shielding is necessary and where something less is entirely satisfactory.

DR. JOHN T. MURPHY, Toledo, Ohio: May I ask Dr. Scheele if the newly designed fluoroscopic unit for the Army has been checked for the effect of radiation on the operator? It looks to me to be the most flagrant violation of the rules of fluoroscopy that I have ever seen.

DR. LEONARD A. SCHEELE, Bethesda, Md.: In answer to Dr. Murphy's question, I do not know whether or not this equipment has been tested for scattering. While we spend a great deal of time talking about protection, many people do little to test exposure actually. Some manufacturers, for example, seem to have made few or no tests of scattering from their equipment under actual or simulated working conditions. They put a little lead here and there and assume that they have provided adequate protection. They often arrange shutters which, when they leave the factory, limit the direct beam to the screen but after a few months no longer limit it on all sides.

DR. MURPHY: Isn't it a fact that, since they have been putting the Bucky diaphragm under the fluoroscopic table, it is impossible to bring a cone into place to shield the lateral and indirect radiation from the fluoroscope?

DR. SCHEELE: It was found that that was the source of much of the secondary radiation and overexposure during roentgenoscopy. We hope that a mechanical means such as a sliding extension on the cone can be devised so that when the Bucky diaphragm is slid into place the extension will be lowered automatically and springs will push it up into place to fill the gap when the plate holder is moved aside.

FALSE POSITIVE SEROLOGIC REACTIONS FOR SYPHILIS

DUE TO SMALLPOX VACCINATIONS (VACCINIA)

FRANCIS W. LYNCH, M.D.

ST. PAUL

RUTH E. BOYNTON, M.D.

AND

ANNE C. KIMBALL, Ph.D.

MINNEAPOLIS

In the past few years there has been a renewal of interest in false positive serologic reactions. Partly because of the increased number of tests performed as a routine on apparently nonsyphilitic persons, there is a better realization of the number of causes of false positive reactions. There are three main groups of such reactions: (1) those due to technical error, a relatively infrequent occurrence; (2) those reactions encountered in persistently false positive human serums resulting from the presence of a reagin-like component which has been demonstrated in various animal serums;¹ (3) those positive serologic reactions which are found in patients with organic disease other than syphilis; they occur regularly in yaws, fairly constantly in leprosy and malaria and less frequently in many other diseases.² Further information and conclusive identification of those diseases causing positive reactions are particularly of clinical interest when the reactions are strongly positive and thus capable of leading to incorrect diagnosis.

With most diseases in which false positive reactions have been frequently reported there is little evidence as to their relative incidence or duration. In some cases the reactions remain positive for only a limited period, as in malaria and infectious mononucleosis. Early reports on serologic studies in these two diseases indicated that only 10 to 20 per cent of the patients gave positive reactions; later studies with frequently repeated tests show that a positive reaction may be expected in almost every malarial patient and in a high proportion of patients with infectious mononucleosis if the specimen is collected at the proper time.

Many acute infectious diseases are known to cause false positive serologic reactions, but vaccinia has not been generally recognized as a cause of such reactions until Moore and his co-workers recently mentioned this possibility, stating that it has been encountered in their clinic.³ There should be particular concern as to the effect of vaccination because it is an immunologic procedure of such general application. Certainly the medical profession should have a peculiar responsibility to see that no patient is wrongly regarded as syphilitic when the false positive serologic reaction may be the result of vaccination.

In 1940 Barnard⁴ reported a case in which positive reactions were observed for more than a month in the

blood of a recently vaccinated person (table 1). There is some doubt that vaccinia caused the positive reactions in this case because the "primary take" did not appear until nearly three weeks after vaccination, but the evidence submitted is reasonably conclusive that vaccinia was the causative factor.

Later in 1940, Bay and Sankstone⁵ decided that the facilities at the Chicago State Hospital made it an "easy matter to make a statistical examination" of this prob-

lem. They studied 100 persons on whose blood Kahn tests were performed on specimens collected at intervals from twenty-nine to seventy-six days from the onset of the vaccination take, and "in no instance was a positive reaction obtained." They concluded that the incidence of such positive reactions must be less than 1 per cent.

Thomas and Garrity⁶ also investigated this problem with a review of the records of 10,000 naval recruits from whom the blood specimens were collected an average of twelve days after vaccination. They found that twenty-three of the twenty-six false positive Kahn reactions were encountered in the group having primary or accelerated vaccination reactions (52 per cent of the total), rather than in the group having immune reactions (48 per cent). There was no appreciable difference between the group showing primary reactions as compared with those showing accelerated reactions. Since no preliminary control studies were performed and only one type of test was used, it was impossible to estimate the percentage incidence of reactions due to vaccinia. In a second report on another group of 10,000 recruits whose blood specimens were collected only before vaccination, six (0.06 per cent) false positive Kahn reactions were recorded as compared with twenty-six (0.26 per cent) in the group vaccinated before the collection of the blood.⁷ Thomas and Garrity describe 1 person whose blood previous to vaccination showed a negative and who gave strong Kahn, Kline and Wassermann reactions three weeks after vaccina-

tion. In this case the Kahn verification test was of the syphilitic type. Reactions became negative within four weeks.

Barnard also mentioned in his report that Giordano has discussed a similar case. Though Giordano's case

has not been formally recorded, he states that in 1935 he observed a patient whose blood reacted positively to a complement fixation and a precipitation test during the period of the local lesion of vaccinia. In 1941 he observed another person who had a false positive reaction associated with vaccinia. In each case the strongly positive reaction gradually changed to negative within forty-five days.⁸

Several years ago the following incident stimulated our interest in this subject. Dr. Mattie J. Bullard of Gary, Ind., then on the staff of the University of Minnesota Students' Health Service, received a report of Kolmer 3+ and Kline 4+ on blood taken from a student who had severe primary vaccinia. The results of subsequent studies are shown in table 2.

Because of the conflicting evidence as to the role of vaccinia in causing false positive reactions, the following study of serologic reactions of a group of youths not previously vaccinated was undertaken. In an effort to exclude the possibility of syphilis or a false positive reaction of undetermined origin, the blood was first tested at the time of inoculation. The subjects were requested to return for a test two weeks later, but in many cases the interval was longer. Those whose serums then gave positive or doubtful reactions were asked to submit to periodic testing until the report

might become negative. In addition to those who showed a doubtful or positive reaction to the diagnostic tests, the studies were repeated on all who showed any reaction to the Kline exclusion test. The time interval of two weeks after inoculation was chosen because it was thought that the patients of Bay and Sankstone may have been studied so long after vaccination that any false positive reactions might already have returned to negative.

All specimens were tested by the Kolmer Wassermann, Kline diagnostic, Hinton and Mazzini tests. Most of the specimens taken after vaccination were tested also by the Eagle and the standard Kahn test.

In any serologic study the reliability of the laboratory performing the tests must be given first consideration. In this study the facilities of the Minnesota Department of Health were used. Serologic tests as performed in these laboratories have been evaluated in the U. S. Public Health Service survey and have been compared with other laboratories within the state. Recently, in a group of patients with early syphilis, the results of standard Kahn tests in these laboratories have been compared with results reported by Dr. Kahn's laboratory on duplicate specimens. The sensitivity and specificity of the tests as performed are shown to be satisfactory.

The physical status of the persons tested also deserves consideration. They were students entering the university who submitted to a routine physical examination and demonstrated no evidence of syphilis. The incidence

of syphilis and of apparently false doubtful or positive reactions has been determined among students entering the university in previous years. Table 3 indicates the status of the group tested in 1939, one year before the present study.

RESULTS OF SURVEY

Among 267 persons in whom primary vaccinia later developed, all specimens taken at the time of inoculation

TABLE 4—Forty-Three False Reactors Encountered in 263 Cases of Vaccinia

	±	+	++	+++	++++	Total
Kline	6	7	0	0	1	14
Kolmer	0	1	1	0	5	7
Hinton	13	6	11	0	1	31
Mazzini	11	7	4	4	2	28

Number of persons in whom this was the highest reaction	14	12	9	2	6	43 (16%)

were reported negative to the Kolmer Wassermann, Hinton and Mazzini tests. One gave a positive reaction (2+) and 3 gave doubtful reactions to the Kline diagnostic test. These 4 reactors are not included in this report except when specifically mentioned.

Of the 263 persons giving no reactions before vaccination, 43 (16 per cent) reacted to one or more of the subsequent tests; 23 (9 per cent) reacted to more than one of the standard serologic procedures. When reactions to all four tests (Kolmer, Kline, Hinton and Mazzini) are considered, a total of eighty positive and doubtful reactions were obtained. Table 4 shows the number and distribution of these reactions.

In the majority of instances the strongest reaction was doubtful or weakly positive; fifty-one of the total of eighty reactions were only ± or 1+; in 26 of the 43 persons the strongest reaction was ± or 1+. Four

following vaccinia. Under the conditions of this study, the Kolmer test was the most specific, since positive reactions were obtained in only 7 persons, but 4+ reactions were noted in 5 of this group. There were 13± or 1+ reactors to the Kline test but only 1 with a stronger reaction. The Hinton and Mazzini tests gave doubtful or positive reactions in 31 and 28 persons respectively. Because the Eagle and Kahn tests were not performed on all specimens, the relative incidence of false positive reactions cannot be determined exactly, though in each case it appears to be intermediate between that of the Kline and that of the Mazzini test. It is interesting to note that all six technics gave this type of false positive reaction to some degree. In several cases strong reactions were given by most of the technics used; such reports might have presented diagnostic problems to the clinician had the specimen been collected as a part of a routine physical examination.

Of the 4 cases in which the diagnostic Kline test gave a reaction before vaccination, 1 showed no reaction to the Kline test after vaccination, though the Mazzini reaction was ±. In a second case (1+) the reaction

Average positivity of reaction to serologic tests for syphilis on the first postvaccination specimen of 271 persons

after vaccination was the same, but in addition a doubtful reaction to the Hinton test was reported. In the remaining 2 cases the Kline reaction was stronger after vaccination, in 1 (±) it became 1+, and in the other Mazzini 1+ and the Hinton and Eagle were each ±. (2+) it became 4+, the Kolmer became 2+, the

Although it was suggested that specimens be collected from twelve to fourteen days after inoculation, not all the patients submitted exactly to this routine and in many cases the first test was performed much later. An attempt has been made to analyze the data so as to determine the incidence of false positive reactions to the various tests with respect to the time interval following vaccination. When the first specimen was submitted from fifteen to twenty-one days after vaccination, positive reactions were more common with the Hinton, Mazzini and Eagle tests. On specimens on which the first test was performed from twenty-two to twenty-eight days after inoculation the Kolmer, Kahn and Kline tests were more likely to give a positive reaction, as shown in the accompanying chart.

The reactions remained positive for as long as two months in many of the persons tested; in a few the reactions were still positive after four months. One (Kline 1+) was still present at one hundred and sixty-four days; in this case reactions with the Kolmer, Kahn,

Kahn				2+	—

plus reactions to any of the tests were reported for only 6 of the 263 persons studied (2.3 per cent). Two plus or stronger reactions were reported on specimens from 17 persons (6.5 per cent).

Among the various tests there was considerable difference in the incidence of the false positive reactions

Eagle and Mazzini tests had been positive at thirty-one days but were negative at one hundred and seven days and again at one hundred and sixty-four days.

The Kahn verification test was performed on the serum of 1 person who has not previously been mentioned in this report because he was in a smaller group studied several months later. On a specimen collected at the time of vaccination and another collected twenty-four days later the Kline diagnostic, Kolmer Wassermann, Hinton and Kahn tests gave negative reactions. A third specimen collected forty-three days after vaccination gave the following reactions: Kline diagnostic 2 +, Kolmer Wassermann negative, Hinton 2 +, Kahn 3 +. A fourth specimen collected forty-seven days after vaccination gave the following reactions: Kline diagnostic doubtful 1 +, Kolmer Wassermann negative, Hinton 3 +, Kahn doubtful 1 +. Kahn verification tests performed on the latter 2 specimens gave "the syphilitic type" reaction. It might be well to recall here that Kahn has pointed out that, while a negative verification test is strongly suggestive of the absence of syphilis, "there are no data available which establish that a positive verification reaction means syphilis in every instance."⁹

COMMENT

The incidence of false positive serologic reactions following vaccinia might have been determined more accurately had this survey been conducted in a different manner. The study served its initial purpose, which was to determine whether such reactions occur. Bay and Sankstone had stated that their number must be less than 1 per cent, but we found false doubtful or positive reactions in 16 per cent of 263 persons studied after primary vaccinia.

Such reactions may be strongly positive and may therefore be a source of confusion to the clinician. They may persist for several months after vaccination. Testing by multiple methods increases the recognized number of positive reactors, as shown by the fact that each of six standard diagnostic technics resulted in this type of false positive reaction. The different tests usually gave varying degrees of reaction; rarely were all tests positive on the same specimen. In the only case in this series in which the Kahn verification test was performed the reaction was of the syphilitic type; Thomas and Garrity⁶ had a similar experience.

Many of the persons in this series were tested only once after vaccination, and it is now known that this test was performed too early to have all the false reactors recognized. The maximum height of positivity was not always recorded at the first test, and it is likely that tests performed on a greater number of specimens would have led to recognition of additional positive reactors among those persons whose first postvaccination test was negative to even the Kline exclusion test.

The data submitted in this report suggest that recognition of the highest possible number of false positive reactions would require the performance of tests on specimens collected more frequently through the period from two to six weeks after vaccination. If this procedure had been followed, the incidence of false reactions would probably have been quite different, and there might also have been a difference in the relative number of false reactions demonstrated by the different diagnostic technics.

ABSTRACT OF DISCUSSION

DR. FRANCIS E. SENEAR, Chicago: Dr. Lynch and his co-workers have presented a careful study of the effect of vaccination in the production of such reactions and, though the first mention of this was made in the literature only last year, make it apparent that vaccinia must be added to the list of conditions capable of producing a false positive reaction for syphilis. Apparently these false positive reactions due to vaccinia follow the pattern of those evoked by some other disorders, a pattern which should always arouse suspicion as to the source of the positive finding. Such reactions are apt to be weakly positive, vary in intensity with different tests or with the same test in different laboratories and show fluctuation in titer from day to day with the same test performed in the same laboratory. In this particular disease it would seem as though we have available a condition which offers great possibilities for study of these biologic false positive reactions, because in the other diseases in which such reactions are obtained we never know whether the patient is to have them or not; we are often uncertain as to the qualification of the laboratory performing previous tests, if we can find that they have been performed previously. But with a disorder of this type, in which, if, as Dr. Lynch and his co-workers' figures show, 16 or 32 per cent of the patients will develop some degree of positive reaction, in which one can check the state of the reaction before the vaccination is performed, it seems to me there is an opportunity for very extended study. One can hardly say yet that the verification reactions, such as Witebsky's or the Kahn verification, can solve this problem. I see Dr. Kline sitting over here and I have no doubt that he will be able to say something about the implications presented by these changes in association with vaccinia. The authors are to be congratulated on having made available so quickly some definite information as to the effect of the commonplace procedure of vaccination in giving rise to false positive reactions for syphilis for temporary, though sometimes prolonged, periods. I would like to speak of the apparently greater specificity in this study of the Kolmer complement fixation reaction. This observation would further support the view held by many observers that, when two or more tests are to be used jointly, one of them should be of a complement fixation type.

DR. B. S. KLINE, Cleveland: Nonspecific reactions in tests for syphilis are easier to explain than are the specific reactions. In every laboratory, even the practicing physician's small laboratory, there are many things which will flocculate the antigen particles in the emulsions used for the detection of syphilitic reagin. These lipid particles have certain physicochemical properties that permit them to be flocculated by dehydrating agents like alcohol and by various electrolytes, including acids and ordinary salts. It is remarkable therefore that these emulsions may be used successfully in the detection of syphilis. Before a false positive test is regarded as a biologic reaction, it is the duty of the serologist to make sure that the reaction is not caused by adventitious material in the antigen. Plain alcoholic extract antigens, for instance, contain so much adventitious material that causes so many nonspecific reactions that they are no longer used in the serodiagnosis of syphilis. Furthermore, my associates and I discontinued the use of Kahn antigen dilution some years ago because in tests at low temperature it gave nonspecific reactions in too great number. Subsequently Kahn antigen was found to contain either insoluble or water soluble impurities. Satisfactory results with this indicator, it was found over ten years ago, can be obtained only at a temperature of 70 F. or over. We have found that even carefully prepared slide test antigen contains impurities that may be removed by extraction with water. At Western Reserve University Dr. Wellman and Dr. Lankelma are making a chemical study of antigens. In another few years they will find a way of isolating the most potent and most specific substance in heart powder in pure form, and then all the headaches for the serologists and a great many for the dermatologists and syphilologists will be eliminated. The use of purified antigens, however, doesn't mean that in malaria and leprosy and in lower animals there won't be a great many nonspecific reactions. As far as testing animal serums is concerned, it should be remembered that the majority of untreated serums of syphilitic

9. Kahn, Reuben L.: A Serologic Verification Test in the Diagnosis of Latent Syphilis. Arch. Dermat. & Syph. 41:817, 1940.

individuals give no reactions with antigen emulsions. The serums must first be heated or there is no reaction. Another way to increase the flocculating capacity of serum is to add a small quantity of electrolyte, such as sodium chloride, in the proper concentration. Horse serum contains more abundant electrolytes apparently than human serum, and because of this there is no more reason for dragging in horse serum to test its ability to flocculate antigen emulsions than for taking calcium chloride or other electrolyte out of a bottle to test its action on antigen emulsions. In leprosy and malaria it may be found that some chemical substance other than reagin is produced in excess and that it thereby causes the flocculation of the antigen particles.

DR. ADOLPH B. LOVEMAN, Louisville, Ky.: Dr. Lynch and his co-workers have rendered a great service to the dermatologists in calling attention to the false positive reactions following vaccination. About four months ago, I saw my first case, in a nurse. In this particular case the Kahn, Kline diagnostic and Kline exclusive tests were all positive but the Kolmer Wassermann test was negative. This was repeated in several laboratories. The Wassermann test in this particular case never became positive. About three months later a soldier came in on a Friday and wished to be married the next day. He also had a positive Kahn, Kline diagnostic and Kline exclusive test and a negative Kolmer Wassermann test. This likewise was repeated in several laboratories. At that time I was suspicious that it was a postvaccinial reaction and we sent the test to Dr. Kahn for his verification test, who reported a biologic type of reaction. This case was rather dramatic in that all tests including a reply from Dr. Kahn were completed in twenty-four hours and the soldier got married according to schedule. These are important cases. In the few selected cases in which repeated tests were made following vaccination for recurrent herpes, in which there were no takes, I did not get any positive reactions from the Kahn, Kline or Wassermann tests.

DR. CHARLES R. REIN, New York: I agree with Dr. Kline that many of the false positive serologic reactions are of the technical type and that a considerable number of these technical false positives will be eliminated with the purification of the antigens. There are, however, a number of diseases and conditions which may produce transient and even permanent biologic false positive reactions. Dr. Lynch and his collaborators have shown today that such false positive reactions may develop following smallpox vaccination. I have encountered many biologic false positive reactions immediately following acute upper respiratory infections. The blood of these patients, however, usually becomes negative in three to four months. Dr. Chargin and I found but few false positive reactions in a group of 119 patients with variella, scarlet fever and measles, in whom the temperature ranged up to 105 F. The clinician must be aware of the fact that biologic false positive reactions may occur and he must be on the lookout for them. Unquestionably, many a person has been stigmatized as syphilitic and indeed given treatment purely on the basis of a positive test occurring in routine examination in the course of or immediately following a non-syphilitic disease.

DR. ARTHUR G. SCHOCH, Dallas, Texas: I would like to ask whether or not in the group of supposedly syphilitic persons the authors established that diagnosis on the basis of serologic results alone? If so, what type of serologic reaction did they consider of such little significance that it was not indicative of true syphilitic infection? Did they do any quantitative determinations? I think we are quibbling when we start differentiating between what constitutes a biologic false positive and a technical false positive reaction and possibly false positive reactions in animals. They are false, and as they are reported to us they are positive. There is a clerical false positive reaction which can be cleared up by merely repeating the test in the same laboratory. Clerical false positive reactions do occur and I would just like to call attention to the fact that sometimes they get the wrong number on the right tube.

DR. FRANCIS W. LYNCH, St. Paul: In reply to Dr. Schoch's question, these are the criteria which we have applied in the diagnosis of syphilis in college students. If they are observed strictly, there is little danger of false diagnosis based on sero-

logic reactions such as we reported today; nevertheless, we believe it worth while to try to demonstrate the cause of every false positive or doubtful reaction. Another question by Dr. Schoch suggested the possible value of applying quantitative studies when dealing with questionable serums. We are unable to report any experience with quantitative tests. Dr. Kline's discussion emphasized the newer technical knowledge which can be applied to prevent or minimize the number of false reactions. Such details are particularly of importance to the serologist. It is only by further recognition of these and similar facts that serologic reports can become more dependable. Yet the clinical syphilologist must of necessity accept the report which is given to him. His primary concern is not the determination of the cause of the falsity but rather the absence or presence of syphilis. Dr. Loveman mentioned two previously unreported cases of false reactions associated with vaccinia. Other clinicians must have had similar experiences but have probably thought that the incidence of such an occurrence was much less than our studies suggest. We have not critically analyzed the reports of serologic studies following immune reactions to vaccinia, but in several instances we have noted doubtful or weakly positive reactions. Dr. Rein mentioned the association between false positive reactions and upper respiratory infections, a point which is also demonstrated in a report by Clifton and Heinz (*THE JOURNAL*, May 4, 1940, p. 1731). It is likely that false reactions accompany many febrile diseases to a much greater extent than has previously been realized.

SOME THERAPEUTIC EXPERIENCES WITH HODGKIN'S DISEASE

OVID O. MEYER, M.D.

MADISON, WIS.

The cause of Hodgkin's disease remains obscure, but the theories of the causative factors are well known. The possible significance of the recent reports of Wise and Poston,¹ who have demonstrated the frequent presence of *Brucella melitensis* in the lymph nodes of patients with lymphogranulomatosis, is yet to be established. These workers have analyzed their results with commendable objectivity and without ascribing a final etiologic relationship to these organisms. Dr. E. A. Birge² has cultured specimens from the lymph nodes of 10 patients with Hodgkin's disease seen at the Wisconsin General Hospital but has been unable to demonstrate *Brucella* organisms. It should be observed, however, that brucellosis is much less common in Wisconsin than in the regions where the patients of Wise and Poston¹ live. This factor has already been weighed by these observers, and further discussion of it is unnecessary.

The therapy of Hodgkin's disease is fairly well standardized at present. It is generally agreed that roentgen ray or radium therapy is indicated in practically all cases. Some authors (Desjardins,³ Jacox, Pierce and Hildreth⁴) advocate early irradiation of all sites of lymph nodes. Others, the majority, prefer to direct treatment only to areas where disease appears. All are in essential agreement that the therapy is merely a palliative except in rare cases and that therefore the aim should be to alleviate symptoms and, if possible,

prolong life. It appears that relief of symptoms is about as satisfactory—and often it is highly satisfactory—when only one or more of the involved areas is treated as when extensive irradiation is employed.

It is not my purpose here, however, to argue for one or the other method of management or to analyze treatment in a series of cases for the purpose of establishing the value of roentgen therapy. Rather, I wish to cite some experiences we have had in order to point out certain lessons learned therefrom: to demonstrate some of the hazards that attend irradiation, to indicate some of the complications that patients experience without apparent untoward effects, to demonstrate the favorable results that may follow properly controlled roentgen therapy and, finally, to urge a more optimistic attitude toward the individual patient, for there is no known prognostic guide which is completely reliable in any given case. Although the average duration of the disease is about three years, neither the patient's age nor sex, the extent of the disease, the status of the blood nor the roentgenographic findings will indicate

projecting from each side at the level of the aortic arch. There was some compression of the trachea near the bifurcation.

Irradiation of the mediastinum was decided on although no lymph node was available for biopsy. After being given two small doses of 100 r each to the anterior and the posterior mediastinum on successive days, the patient had severe dyspnea and signs of complete atelectasis of the right lung. She was unimproved for four days and then began to cough violently, raising much mucus, and the lung reexpanded. Therapy was then resumed, and eight more treatments were given without untoward effects.

On Feb. 1, 1939 a roentgenogram of the chest showed definite shrinkage of the mediastinal mass and there was subjective improvement. Two months later she was readmitted with the complaint of recurrence of difficulty in breathing. Since her admission of 1938 she had had tenderness and enlargement of the lymph nodes in the right axilla and the right side of the neck. Biopsy of a supraclavicular node showed endothelial proliferation, many Sternberg-Reed cells and eosinophils and diffuse infiltration by polymorphonuclear leukocytes. There was frank pus about the node, from which diphtheroid organisms grew on culture. A roentgenogram of the chest showed

Fig. 2.—Appearance of M. K.'s chest after irradiation of the mediastinum, demonstrating atelectasis of the right lung.

Fig. 3.—Appearance of M. K.'s chest Feb. 1, 1939, two months after therapy.

the expectancy of comfortable life. Hence the physician is justified in taking a more optimistic view in his dealings with the individual patient than he usually does at present.

REPORT OF CASES

CASE 1.—Mrs. M. K., a housewife aged 29 who had been a registered nurse, was admitted to the hospital in November 1938. In May 1937, while pregnant, she had a pain in the chest just behind the sternum. After the birth of her child in September, the pain became worse. Subsequently it subsided, but five weeks before admission she had shortness of breath. As this progressed, a productive cough developed. A roentgenogram of the chest showed widening of the mediastinum. The menses had ceased again four months before she came under my observation.

Physical examination showed the patient to be well developed, undernourished and rather uncomfortable and to have slight cyanosis, cough and, on slight exertion, severe dyspnea. The veins of the neck were distended. There were signs of a mediastinal mass, but there was no enlargement of the superficial lymph nodes. Pelvic examination revealed enlargement of the uterus to the size produced by a 3 or 4 month pregnancy.

The blood showed a hemoglobin content of 10.6 Gm., 3,620,000 erythrocytes and 20,700 leukocytes, with 92 per cent neutrophils. An Aschheim-Zondek test gave positive results. Roentgenograms of the chest showed a mass of soft tissue

that the mediastinum had become enlarged to approximately its former size.

Another course of roentgen therapy was started. After three treatments of 150 r to the anterior and the posterior mediastinum given over four days, signs of atelectasis of the middle and lower lobes of the right lung developed. A thick, gummy material was aspirated with a bronchoscope. The patient was then able to complete the total course of thirteen treatments uneventfully.

In May 1939 the patient was delivered of a normal child. In June she returned to the hospital and received roentgen therapy to the mediastinum and the right axilla. In October she returned once more, with signs of nearly complete atelectasis of the right lung. The mediastinal mass was not especially large, but further therapy was given. Apparently immediately thereafter, the patient became pregnant for the third time, and in January 1940 a therapeutic abortion was performed.

Subsequently, she was admitted to the hospital on four occasions. Atelectasis of the right lung persisted. At one time peribronchial fibrosis of the left lung was demonstrated. Fluid accumulated in the right pleural cavity from time to time. Ascites developed, and paracentesis was required. Considerable deformity of the chest, with scoliosis, appeared.

The patient's final admission to the hospital occurred in February 1941. She had lost weight and was pale and had anasarca. There was gross enlargement of a left supraclavicular node. The atelectasis of the right lung continued, and a roent-

genogram of the chest showed a well defined, rounded rarefaction about 4 cm. in diameter just below the level of the left clavicle. The patient died on February 19.

Postmortem examination revealed no disease of the lymph nodes except in the mediastinum. All bacteriologic studies, including search for tubercle bacilli, gave negative results. There was extensive fibrosis of the right lung, with fibrosis about the large vessels, which showed endarteritis. These changes had produced an increased load on the heart, and chronic cor pulmonale resulted. The cavity in the left lung showed a wall of granulation tissue about an abscess. In the wall there were many atypical reticuloendothelial cells.

COMMENT

This case demonstrates several points. The patient had three pregnancies, of which two went to term, during the course of her illness. It was not demonstrable that they affected the illness favorably or unfavorably. One does not, of course, know what the outcome would have been had the pregnancies not existed, but the duration of illness was about forty-five months, which is as long as the average.

CASE 2.—Mrs. H. J., a housewife aged 40, was referred on July 25, 1940 to the Wisconsin General Hospital from a sanatorium where a diagnosis of pulmonary tuberculosis and exfoliative dermatitis had been made. Previously she had had pruritic lesions on the forearms and the scalp, had fatigued easily and had experienced night sweats and pain in the right part of the thorax due to pleurisy. She was sent to us because of the troublesome condition of the skin. There was no history of contact with tuberculosis.

Physical examination revealed emaciation and a severe generalized dermatitis involving the scalp particularly. There was generalized erythema, with thickening and scaling and bullous lesions on the fingers. There were signs suggesting infiltration at the apex of the right lung. Enlarged lymph nodes were noted in the cervical, inguinal and epitrochlear regions, the largest less than 2 cm. in diameter. The liver was palpable; the spleen was not palpated.

Laboratory studies revealed a hemoglobin content of 11.1 Gm.; 5,330,000 erythrocytes and 10,600 leukocytes, with 80 per cent neutrophils, 3 per cent monocytes, 8 per cent lymphocytes, 8 per cent eosinophils and 1 per cent basophils. Many examinations of the sputum and the gastric contents were nega-

Fig. 4.—Appearance of M. K.'s chest in December 1939, when atelectasis had become permanent.

Fig. 5.—Appearance of M. K.'s chest eight days before death. There are definite thoracic scoliosis, persistence of atelectasis and a cavity in the left infraclavicular region close to the sternum.

Fig. 6.—Appearance of H. J.'s chest at the time of first admission, July 1940.

The production of atelectasis after irradiation of the mediastinal masses is a hazard that must always be considered. It is supposedly due to reaction and swelling of the mass, with bronchial compression. Furthermore, there may be bronchial reaction and hypersecretion. Actually, however, atelectasis is not common, and it is rather astonishing that in the foregoing case small doses cautiously applied repeatedly produced it. When mediastinal lymphomatous masses exist, the possibility of beginning therapy at a distant site or with general irradiation should perhaps be considered.

Finally, the pathologic changes are of interest. The cavitation appears to be a result of actual infiltration of the lung with the tissue of Hodgkin's disease, with perhaps a secondary factor of infection. It is well recognized that pulmonary involvement occurs in Hodgkin's disease. The additional grosser findings of extensive fibrosis and endarteritis, which were, at least in large part, a result of intensive irradiation, the total dose over the two years being large, with resultant chronic cor pulmonale, emphasize another hazard of irradiation to the mediastinum and the lungs.

For tubercle bacilli, and inoculated guinea pigs remained normal. Examinations were negative for fungi. A stereoscopic roentgenogram of the chest showed a conglomerate opacity at the periphery of the fourth interspace laterally and some rather isolated areas of nodular infiltration in the midportions and in the lower part of the right lung field. On the left there was a somewhat homogeneous opacity extending from the first interspace anteriorly to the level of the fifth rib. There was pleural thickening peripherally in the lower half of the left lung field. A roentgenographic study of progress on September 7 showed that the condition had cleared in some areas and had extended in others. Bronchoscopic study at this time revealed no abnormality.

It was established that the dermatitis was due to contact with a proprietary hair lotion containing marrow oil. This lesion cleared with local applications and the avoidance of contact with oils. Some months later a patch test with the marrow oil of the shampoo produced a violent reaction.

An inguinal lymph node was removed on August 22, and microscopic study of this revealed chronic hyperplastic lymphadenitis.

Since the pulmonary lesions persisted and no explanation for them was available, an epitrochlear node was excised and examined microscopically. This showed scarring, some loss of structure, eosinophils, endothelial proliferation and Sternberg-

Reed cells. Dr. C. H. Bunting and Dr. W. D. Stovall agreed that the changes were those of Hodgkin's disease.

The patient was then given ten treatments of 150 r each to the anterior and the posterior part of the right lung alone over the twelve days between September 26 and October 7. The total dose was 3,000 r. A roentgenogram taken on October 8 showed a clearing of the infiltrative change in both

lung fields. Only a few small areas remained in each lung. The patient was again seen on November 7. She had felt well in the interval and had gained 15 pounds (6.8 Kg.). A few scattered superficial nodes were palpable. Roentgenograms showed that the lungs were still clear save for a few small infiltrations. The superior mediastinal shadow had broadened slightly, particularly on the right. It was decided not to irradiate at this time, and the patient was discharged. She has remained well, and another roentgenogram of the chest made in February of this year showed the lungs to be normal.

Fig. 7.—Appearance of H. J.'s chest in February 1941. A roentgenogram in October 1940 had shown a similar degree of clearing.

COMMENT

The illness of this patient was a diagnostic puzzle for many weeks after admission. The suspicion of Hodgkin's disease, which was slow in developing, was allayed by the first biopsy, which revealed lymphadenitis. Examination of inguinal nodes is untrustworthy; a node from any site but the groin is usually more satisfactory, for often the inguinal node will show lymphadenitis, as it did in this case, whereas nodes from other sites will be affected by the primary disease.

Hodgkin's disease, in the opinion of Piney,⁵ is a disease of the reticuloendothelial system. Hence manifestations of the disease may predominate at any of several sites, including the lungs. One must recognize that intrathoracic involvement may be of many types other than disease of the mediastinal lymph nodes.

Moolten⁶ has discussed the subject at length and has recorded the many changes, infiltrative, miliary and pneumonic, as well as invasion from mediastinal lymph nodes, that may occur. Versé⁷ has stated that in about 10 per cent of cases of Hodgkin's disease of the lung the primary lesion is pulmonary.

The response to irradiation in case 2 was striking and gratifying. Possibly it was overconservative to limit irradiation to one lung, but no disadvantage could result from this caution, and the response in the two lungs was not completely unexpected in view of the diagnosis, since occasionally one sees an effect of treatment at a distance from the primary site of irradiation in cases of lymphoblastoma. Unquestionably a certain amount of scattered radiation reached the left lung.

CASE 3.—E. K., a boy aged 14 who had played football on his high school team, was admitted to the hospital on Nov. 26, 1940. In 1933 he had noticed a progressive painless enlargement of lymph nodes in his neck. A biopsy was done, a diagnosis of Hodgkin's disease was made and roentgen therapy was instituted, with prompt disappearance of the masses. Thereafter he had treatments when necessary. In July 1940 he had pains in the back and in the calves of the legs which rapidly became more severe and were stabbing on movement of the hips. Weakness in the lower extremities became severe, and from July until admission the patient had been bedridden. His physicians were pessimistic regarding his condition, and only symptomatic therapy was instituted.

Physical examination revealed that the patient was uncomfortable, pallid and bedridden, with firm, nontender, discrete, movable nodes, up to 5 cm. in diameter, in the left cervical region. The spleen and the liver were palpable below the costal margin. There was weakness of the legs, especially of the flexors and the abductors of the thigh, the extensors of the leg, and the dorsal and plantar flexors of the feet and toes. The knee jerk and achilles tendon reflexes were exaggerated, and there was bilateral ankle and patellar clonus. The Babinski reflex was present, and confirmatory tests gave positive results. The muscles of the calves were somewhat atrophic. The sensory picture was bizarre, with widespread hypesthesia, slight at the level of the eighth dorsal vertebra persisting to the lower part of the abdomen, at the level of the twelfth dorsal vertebra, where there were normal or hyperesthetic reactions. In the legs the sensory changes took place primarily at the levels of the third and fourth lumbar vertebrae. The vibratory sense was impaired in both the lower extremities. The neurologic consultant, Dr. M. J. Musser, expressed the belief that the patient had intramedullary lesions at the levels of the fifth and sixth dorsal vertebrae and in addition an extramedullary lesion affecting primarily the fourth lumbar vertebra. Motion of the spine was limited by pain, and there was a gibbus between the second and third lumbar vertebrae.

The blood showed a hemoglobin content of 12.2 Gm., 4,690,000 erythrocytes and 13,200 leukocytes, with 74 per cent neutrophils. A roentgenogram of the spine showed an early sclerotic density of the body of the second and sixth dorsal vertebrae. There were a distinct gibbus at the level of the third lumbar vertebra and minimal changes in the body of this vertebra. A roentgenogram of the chest showed a slight increase in the mediastinal shadow indicative of enlargement of lymph nodes.

The patient received six treatments of 200 r each to the dorsal and lumbar portion of the spine. Before his discharge from the hospital on December 12 most of the pain in the back had subsided and some muscular power had been regained.

Two months later he returned to the outpatient department. All pain had subsided, he had gained about 20 pounds (9.1 Kg.) and he was up and about on crutches. The liver and the spleen were no longer palpable, and there was no enlargement of lymph nodes. There was no spinal tenderness. Reflexes were still hyperactive in the lower extremities, and there was a Babinski reflex on the left. Minimal sensory changes and impairment of the vibratory sense persisted below the knees.

The hemoglobin content was 15 Gm. and the erythrocyte count 4,170,000. No treatment was advised, and the patient returned home.

He came to the outpatient department again on April 2, walking with a wide base, without crutches. He had gained 17 pounds (7.7 Kg.) and now weighed 153 pounds (69.4 Kg.). Deep tendon reflexes were about normal; the Babinski reflex

Fig. 9.—The sixth dorsal vertebra of E. K., before and after irradiation.

was present bilaterally. There was no enlargement either of lymph nodes or of the spleen. The liver was just palpable. Roentgenograms of the spine showed a return to normal of the appearance of the vertebrae. The blood count was essentially normal.

COMMENT

Case 3 emphasizes the striking improvement that may follow irradiation of the spine when lesions of the spinal cord exist. Vertebral lesions in Hodgkin's disease are common. If treatment is not vigorously instituted, compression fracture and paralysis may result. In this case there was nothing to suggest that this had occurred, but disease of the spinal cord existed as a result of lymphogranulomatous involvement. Lesions of the cord are not rare; often laminectomy has been done and tissue removed surgically. This procedure is ordinarily unnecessary, especially if proper treatment is instituted early. Fortunately it was possible to repair the damage in case 3.

This case also emphasizes how difficult the prognosis of Hodgkin's disease is and how improper is an attitude of complete pessimism. The boy had Hodgkin's disease first when he was 7. The consensus is that children and young adults are more likely to have a shorter span of life than those who develop the disease at later ages. But one cannot say that this will be true in any specific case. Further, even though, as is not infrequently the case, involvement of the vertebrae and the cord is likely to be a late manifestation of the disease, the laissez-faire attitude is not justifiable. With only a modicum of roentgen therapy patient 3 has already had months⁸ of freedom from pain, and he is up and about after previous months of unnecessary pain and the restrictions of a bedridden invalid.

CONCLUSION

No doubt almost every one who treats Hodgkin's disease could duplicate experiences such as those I have set down, each of which furnishes its lesson. In emphasizing the hazards and the desirability of greater optimism I have had no intention of minimizing the importance of continued search for the cause of Hodgkin's disease and better therapeutic measures or cure.

8. This patient was seen again July 24, and he is still well. He has received no irradiation since December 1940.

ABSTRACT OF DISCUSSION

DR. RAPHAEL ISAACS, Chicago: Dr. Meyer has chosen his patients well in order to illustrate certain points. A problem which comes up frequently is the question of Hodgkin's disease and pregnancy, and the question also of pregnancy and roentgen treatment. The patient described by Dr. Meyer received thirteen roentgen treatments while she was pregnant. I judge this would amount to almost 2,000 roentgens given to the patient during pregnancy, and presumably a normal child was born. That point is important, because there is much in the literature to make one worry about whether roentgen rays will affect the child or not. The second point is that the literature seems to indicate that Hodgkin's disease is aggravated by pregnancy. However, this patient appeared to go through pregnancy without any immediate exacerbation of the disease. Dr. Meyer points out the presence of Hodgkin's lesions in the lungs and the danger of atelectasis. The involvement of the bone and its dramatic improvement with roentgen therapy I can confirm with patients in my own experience, and the outlook sometimes is good. Pregnancy during Hodgkin's disease is quite different from pregnancy and lymphosarcoma. Lymphosarcoma may recede during pregnancy, with apparent disappearance of all signs of the disease. The lymph glands may become normal in size, but they enlarge again after the baby is born. What does one do to Hodgkin's tissue when one gives roentgen treatment? Presumably one decreases the number of lymphocytes in the Hodgkin's glands without gross effect on fibrous tissue. Fibrous tissue is the type of tissue which forms the bulk of the large glands. This is an important point to remember in trying to reduce a gland to normal size. It is felt that Hodgkin's disease is more of an infection than a neoplastic disease, and for that reason the future is looked forward to with more hopeful prognosis. Hodgkin's disease is twice as frequent in males as in females, and this will, I think, furnish a clue to treatment in the future. The characteristics of Hodgkin's tissue as it invades other tissue is not like a neoplastic cell invading tissue, but it resembles what would happen if the invaded tissue had become infected.

DR. W. EDWARD CHAMBERLIN, Philadelphia: Dr. Meyer is right in pointing out that we learn about Hodgkin's disease by these individual cases. His 3 cases illustrate very different types of Hodgkin's disease and very different responses to therapy. I suppose the reason the manifestations of Hodgkin's disease are so protean is that it is a disease of the reticulo-endothelial tissue, which, after all, is found in most of the organs of the body. Cases have been seen in which the disease simulated Riedel's struma. Even the surgical pathologist, looking at tissue removed for clinical diagnosis, agreed that the tissue was probably Riedel's struma, but we found later on it was Hodgkin's disease primary in the thyroid gland. I had a case that simulated scabies for a long time. The patient was over a year in the skin clinic with itching of the skin. There were no glandular masses anywhere and it was thought to be scabies because of the intense itching. It turned out to be Hodgkin's disease and manifested itself in the thorax and peripheral lymph nodes. There is a great deal of difference in the roentgen ray diagnostic aspects of primary Hodgkin's disease in the lung and in the mediastinum. In the mediastinum a typical smoothly outlined, apparently encapsulated mass is seen, while, if the lung is involved, finger-like infiltration is noted in the lung tissue. I saw a case in which it simulated breast cancer in a woman aged 37 because it was not believed that the mass in the axilla came before the mass in the breast. Occasionally there are cases in which there are no masses at all. There was such a case at Stanford about fifteen years ago. Patients die with various diagnoses when really the condition is Hodgkin's disease. There are many diagnoses missed. One has to be more on the lookout for Hodgkin's disease. The diagnosis is not going to be made unless one remembers that it is one of the possibilities in these cases with such remarkable protean manifestations. I think Dr. Meyer is close to the secret of success in treatment, but I think he has to go a step further. He is willing to let a patient go without treatment at times, and I think that is important. One rule is important in the management

of Hodgkin's disease. We are only palliating; we are not curing, and therefore we must try to make it definitely palliative. Big doses sometimes make the patient feel miserable, and remarkable results can be obtained with minute doses. I have given as little as 20 roentgens to a lesion and have seen it regress. The rule is this: Try to get along with the smallest possible individual and total dose that will keep the patient comfortable.

CANCER OF THE LOWER LIP

TREATMENT WITH RADIATION

JOHN H. LAMB, M.D.

AND

WILLIAM E. EASTLAND, M.D.

OKLAHOMA CITY

The choice of treatment for cancer of the lower lip varies widely in the different medical centers where large numbers of patients with this condition are seen. Physicians who attempted the use of radium and roentgen rays with inadequate doses in the early periods of these forms of therapy immediately turned to more satisfactory means of treating malignant lesions by actual cauterization and plastic surgical operations. These methods have been carefully developed, and their application is successful in producing cures.¹ Equally successful has been the use of irradiation by roentgen rays and radium when employed in sufficient doses.²

In our hands, the most successful treatment for cancer of the lip has been a combination of the gamma rays of radium with unfiltered or lightly filtered roentgen rays. This will provide an adequate dose by treatment on successive days to effect a total, continuous or massive dose, which is infinitely better than the small, inadequate doses formerly given at intervals of one to six weeks. Insufficient doses at short intervals, as employed by the so-called "conservative" radiotherapists, simply encourages the tumor to become radio-resistant, as was proved experimentally by Motttram.³ Yet Martin⁴ stated that as far back as 1913, Pusey⁵ had devised a technic which gave a dose high enough to effect a cure but which, for some reason, was not then generally adopted.

There is no part of the body where cancer can be treated by radiation so satisfactorily as on the lip. This is because (1) the blood supply is good, giving a healthy tissue bed—a prerequisite for the establishment of radio-sensitivity or a good effect from radium; (2) application is easy, and (3) metastasis does not take place until late in 90 per cent of the cases.

Because of lack of space, this article has been abbreviated for publication in THE JOURNAL. The complete article appears in the authors' reprints.

Classification.—Lain⁶ reviewed the early period (1909 to 1921 inclusive) of the radiation treatment of cancer of the lip and concluded that on the whole the final results had been satisfactory. He stressed the importance of proper dosage and classified the lesions according to the extent of the clinical involvement. Other more recent classifications⁷ have been based on measurements or on the duration and extent of the glandular involvement. We are convinced that a description of clinical characteristics is of the utmost importance, even though a simpler classification may be necessary when one tabulates results.

PRECANCEROUS CONDITIONS

The various kinds of cancer of the lip all seem to originate in certain precancerous conditions such as leukoplakia, sun or "fever" blisters, senile keratoses, keratoses due to irritation from jagged or broken teeth and granulomas arising in razor cuts or from simple scratches.

Leukoplakia.—The lips of many pipe and cigaret smokers show a thin type of leukoplakia, both on the vermilion border and on the mucous surface. This is distributed over definite areas of the lip, usually near the place where pipe, cigar or cigaret is habitually held. At first these are but thin, bluish white spots which are soft and seem to fade into the surrounding labial surface. As the condition develops, the spots coalesce to form small plaques with well margined borders. At the point receiving greatest stimulation—the "smoker's patch"—there is a gradual thickening into leukokeratosis, a slightly warty proliferation spreading at first laterally in all directions, perhaps remaining in this stage for some time but eventually forming an indurated border with a rolled edge and a downgrowth beneath the leukokeratotic surfaces. Such lesions do not ulcerate or metastasize early but may suddenly begin to grow rapidly with a deep proliferation.

Actinic Lesions (Sun or "Fever" Blisters, Actinic Keratoses).—These were by far the most numerous early precanceroses noticed in our series. The patient's description of the earliest lesions is a blistering or sunburn in several areas on the vermilion border of the lower lip. Some had chronic actinic cheilitis of the entire exposed surface of the lip, with dryness, scaling and fissuring. With continued exposure to the sun a more persistent lesion is formed in one area. On examination this is seen to be an erosion, not a herpetic condition. There is usually some degree of superficial crusting; hence the term "fever" blister as used by the patients. These lesions heal but recur with exposure to the sun, after which two types of lesion seem to follow. The first is the formation over the blistered area of a keratotic scale which when peeled off yields a bleeding surface (keratosis solaris). Later a superficial induration spreads under this keratoma and infiltrates into the substance of the lip until a button-shaped induration can be palpated beneath the epithelium. The second type of lesion is one that sometimes develops rather rapidly from the sun erosion. After several recurrences, according to the patients, the erosion fails to heal and progresses into a denuded, slightly elevated, crusted, indurated growth. As this proliferates the borders become slightly elevated and infiltrated. Secondary infection, which invariably takes

place, may eventually cause the growth to become fungating. Metastasis sometimes has been noted when the lesion was less than 2 cm. in diameter. This type is also found among the younger, more active patients. A pathologic study is being made on such lesions, but no discussion can be made in this paper except to state that the pathologic process of an early sun blister is similar to that produced by mechanical or chemical burns.

Senile Keratoses.—These are a frequent precursor of cancer of the lip in the aged. Ewing⁸ mentioned cancer arising from seborrheic keratoses on the lip. In none of our cases did the cancer originate in the greasy, somewhat verrucous, yellowish brown, loosely adherent lesion known as seborrheic keratosis. But the dry, scaly, senile keratosis which is firmly adherent to the lip and is gray or brownish yellow may develop into a slightly elevated, indurated, button-like lesion which may proliferate in all directions and project 2 or 3 mm into the substance of the lip before any ulceration takes place. These lesions often become large papillary growths which rise above the surface of the lip and form layers of keratin almost comparable to a cutaneous horn. Lesions arising from senile keratoses in the aged patient may reach huge proportions without showing any evidence of metastasis.

Leukokeratotic Areas.—These may arise from trauma from jagged or broken teeth and seem to have a predilection for the buccal mucosa of the lip, where they grow rapidly, ulcerate and metastasize early.

Superficial Granulomas.—On the lip these are the result of scratches, razor cuts and other abrasions. They tend to remain not more than 1 or 2 mm. in thickness and proliferate peripherally on the surface. They soon form a thin, soft, granulomatous mass which bleeds easily and becomes ulcerated and secondarily infected; the infection may lead to extensive local suppuration. The lymph glands are usually palpable because of an inflammatory reaction to this infection.

MATERIAL

The patients studied are classified according to the size of the lesion and the extent of involvement of the lymph nodes. They were all seen in private practice, and discussion of any patients from the outpatient department of the university hospitals will be so identified. We have found our patients more easily classified in the following manner:

Group 1—lesion 1.5 cm. or less, glands not palpable.

Group 2—lesion 1.5 cm. or less, glands palpable.

Group 3—lesion larger than 1.5 cm., glands not palpable.

Group 4—lesion larger than 1.5 cm., glands palpable.

In our series, 177 of the patients were in group 1, 48 were in group 2, 46 were in group 3 and 47 were in group 4.

The lesions of many patients of groups 1 and 2 were indurated, smooth, button-like proliferations. Some had become ulcerated because of previous treatment with plaster. Many were slightly elevated, with warty or scaly keratotic surfaces, indurated bases and rolled borders.

In groups 3 and 4 the patients had larger, ulcerative, granulomatous growths. Several growths extended over one third of the surface of the lip, while one lesion involved one half and another fully two thirds of the surface.

Fig 1—Three patients treated by well filtered radium and roentgen rays. a, patient in group 3 treated by interstitial needles and roentgen rays, with two year survival; b, patient in group 4 treated by external application of radium and roentgen rays, with five year survival; c, patient in group 4 treated by interstitial needles and roentgen rays, with four year survival.

Our patients were studied to determine the type of skin, the incidence of dental caries, the possible influence of their occupations, the kind of smoking (pipe, cigar or cigaret), the involvement of the lymph nodes and finally the evolution of the intensity of treatment with its subsequent results. The youngest patient treated was 20 years old and the oldest 85 (table 1). The average age was 53 years.

Age is a factor in selecting the type of treatment. Radiation sequelae as a contraindication to radiation therapy are negligible. Under less favorable circum-

⁸ Ewing, James. Neoplastic Diseases, ed 4, Philadelphia & London, W. B. Saunders Company, 1940.

stances it is possible to obtain sequelae such as telangiectasia and slight atrophy. We have examined younger patients with tender skins who had been treated twenty years before by beta radiation and unfiltered

containing a skin-colored product. Patients with skin sensitive to actinic rays are advised to wear large hats and to use these creams or lipsticks several times a day. They are advised also to grow a heavy mustache, when possible, to protect the lips from the sun. Sixty patients in our study reported sun or "fever" blisters as initial lesions.

The use of tobacco predisposes to leukoplakia, which leads to leukokeratosis and finally to carcinoma. Sixty-three of our patients were cigaret smokers; 52 used a pipe, and 17, cigars. There were 132 smokers altogether. Thirteen patients reported previous abrasions with the razor, while many had dental caries or irregular or sharp teeth. Those having the worst oral conditions were advised to have oral hygiene and extraction of decayed teeth before high voltage roentgen therapy for metastasis was prescribed, in order to prevent necrosis of bone. Otherwise the mouth was not cleaned up until after the lip had been irradiated and was entirely well. Fifteen patients had been treated previously with pastes and plasters, therapy which, as Broders,⁹ Lain⁶ and others have agreed, lessens the chance of recovery. Eleven had been treated by fulguration (electric needle), 4 with acid, 1 with phenol and 1 with the silver nitrate stick. Six had received small repeated doses of roentgen rays in another clinic.

BIOPSY

There is general agreement among all who treat cancer that biopsy should be done whenever possible,

Fig. 2.—An early infiltrating lesion which shows disorganized, fairly anaplastic prickly cells breaking through the basal cell membrane. Inter-cellular edema with loss of prickly cells in some areas may be noted. One well formed epithelial pearl may be seen in the lower portion.

roentgen rays, and most of them still showed soft, pliable scars with excellent cosmetic results (only a few presenting small, telangiectatic areas), thereby demonstrating that the earlier technic produced many good results. Nowadays in younger patients (20 to 35 years old) we confine the treatment to gamma radiation, using interstitial needles or well filtered radium plaques.

PREDISPOSING CAUSES

Fair-skinned persons are particularly susceptible to cancer of the lip. Only 2 in our series were full-blooded Indians, and the growths occurred in the scars of old chronic lupus erythematosus. Only 4 women were found to have cancer of the lower lip. One hundred and four of our patients were farmers, showing again that occupation does play an important part. The chance of acquiring a malignant neoplasm of the lip is in proportion to the extent of exposure to actinic rays. The problem of actinic rays unfavorably affecting areas of radiodermatitis has been overcome largely in radiation treatment by improvements in technic, so that few serious consequences in this respect are now encountered. Sensitive patients must lead a less active life and so are advised to rest during the time of most intense exposure to the sun, to work only early and late in the day and to protect their lips with sunburn creams in which are incorporated bismuth oxylchloride, quinine or tannic acid. One of the agents now being tried for reflecting actinic rays is a proprietary preparation made in the form of a lipstick

but it has not been our custom to take specimens for biopsy in all cases as a routine procedure. The largest number of lesions in patients of groups 1 and 2 showed

9. Broders, A. C.: Squamous Cell Epithelioma of the Lip. *J. A. M. A.* 74: 656 (March 6) 1920.

no ulceration, and nonulcerated lesions were the type on which biopsy was not usually performed.

Since we began to use small interstitial needles biopsy has become a much simpler procedure and is performed more often, for in any event the lip must have local anesthesia for the placement of the needles, and a specimen for biopsy can be removed at the same time.

GRADING

The importance of grading tumors according to Broders' classification of adult and embryonal cells is accepted with skepticism by many pathologists, but this method of classification has been a valuable contribution to the study of the pathology of tumors. In his excellent review⁹ of the pathology of cancer of the lip, 62 per cent of the tumors were of grade 2 and 21 per cent were of grade 3.

Mekie¹⁰ expressed the belief that the idea of differentiation of tumors is not the whole story. If the histogenesis of tumors is to be understood, the relationship of the squamous cells to the basal cells must be understood. He considered the basal cells as the important ones, since they alone possess the power of reproduction. The basal cell is the most highly differentiated in squamous epithelium, and the more superficial layers (stratum lucidum and stratum corneum) represent a "degeneration" which culminates in keratinization. He expressed the opinion that the tumor bed and the anaplasia of the basal cells in squamous cell carcinoma are of utmost importance.

Grading is considered to be of prognostic value. Broders found metastasis in 11 per cent of patients with tumors of grade 1 and grade 2, while 66 per cent with tumors of grade 3 or grade 4 had metastasis. But examination of 20 patients with metastasis by Kennedy¹¹ showed 18 with grade 1 and 2 with grade 2 cancers. Thus, in this small group it did not seem that grading played an important part in determining the danger of metastasis.

There are many other factors of equal prognostic value of a clinical nature. The type of tumor bed (MacKee and Cipollaro¹²) is of as great importance to the radiotherapist as the percentage of cells which are adult or embryonal. The gross appearance and clinical course of the tumor also are of much prognostic value.

TISSUE STUDIED

Seventy-one microscopic sections from lesions of the lower lip were studied. Forty-one were from private patients and 30 from outpatients (University Hos-

pitals). Biopsy was done on only a small percentage of the 225 patients in groups 1 and 2. Of the 93 in groups 3 and 4 less than 50 per cent had sections made.

MODES OF USING RADIUM

1. *Application of Radium to the Surface.*—For the application of "cross fire" therapy, no part of the body is more satisfactory than the lip. Radium plaques are used in two forms approximately fitting the lesions. For larger growths, two 10 mg. half strength plaques and one 5 mg. plaque are used in the form of a saddle, the two 10 mg. plaques being placed anteriorly and posteriorly with the 5 mg. applicator on top. Two mm. of lead is used as a filter on all plaques, only the harder gamma rays thus being utilized. An additional distance of 1 to 1.5 cm. from the skin to the plaque is supplied by enclosing gauze between the filter and the nonmetallic rubber. It is left in place a long enough time to give the predetermined dose of 1,400 to 2,500 milligram hours, which is usually three or four days. During use of the saddle applicator, particular attention to the natural fullness and thickness of the lip is important, as the dose varies in proportion to the diameter of the lip.

2. *Use of the Interstitial Needle.*—Our needles vary in size, having an over-all length of 11, 21 or 28 mm. and a wall thickness of 0.5 mm. of platinum. The radium element is distributed so that there is 1 mg. to each centimeter of active length. This is slightly more radium element than there was in the original needles used by Cade,¹³ but this distribution was used since it was found that the radium in a 1 cm. needle centrally placed for seven days would satisfactorily destroy 1 cc. of squamous cell carcinoma. In accordance with the previous work of other radiotherapists,¹⁴ we have employed the following plan of irradiation: The entire tumor is divided into imaginary spheres of 1 cc. each. If the lesion is sufficiently wide, needles are placed in parallel rows, 1 cm. apart, running the length of the lesion. A second or a third plane of needles 1 cm. inferior to the plane first implanted is used if necessitated by the depth of the lesion. Thus at least 168 milligram hours of radium can be administered to each sphere or cubic centimeter of tissue. In order not to undertreat the peripheral cells of a tumor, the outer

needles are placed 0.5 cm. beyond the border of the lesion in apparently normal skin.

Interstitial needles are of particular value in the treatment of recurrences of lesions previously inadequately treated by roentgen rays or by too small external applications of radium. Serious cutaneous reactions

have been avoided by implanting the needles as deeply as possible while yet approximating the lower border of the lesions. Such placement allows the major effect of radiation to be utilized at a proper depth, whereas the amount of radiation affecting the skin will be small proportionately. We get better cosmetic results

in utilizing the same principle by interstitial irradiation, avoiding telangiectasia, pigmentary changes and atrophy. The ganuna rays from this small concentration of radium over a more prolonged time seem to fulfil Regaud's¹⁵ concept of bombarding the cells during the stage of mitosis. Interstitial irradiation has been used in our series for six years. Fifty-two patients were treated by this method, and for only 1 was failure to cure the primary lesion recorded. This patient had been treated previously several times by external application of small, inadequate doses of radium. Interstitial irradiation does not require hospitalization, though the area under treatment is dressed daily with a bland ointment. If the lesion is secondarily infected, filtered roentgen ray treatment is given for several days preceding the placement of the needles, and moist dressings of boric acid or sulfanilamide and glycerin are used.

In our series there have been no cases of lymphangitis or local suppuration in the lip resulting from the interstitial implantation of radium. Patients have but little discomfort, and the procedure saves valuable time formerly lost each day in removing the surface applicator for shaving and eating.

TREATMENT OF GROUP 1

Group 1 consisted of patients whose lesions were localized, indurated and not more than 1.5 cm. in diameter. 1. If the lesion is a papillary outgrowth, superficial in type, 1 cm. or less in diameter and not over 1 to 3 mm. in thickness, unfiltered roentgen rays are used, with a force of 100 kilovolts and an intensity of 3 milliamperes, in 3 to 5 skin erythema doses (800 to 1,200 r). The surrounding normal tissue is shielded within 2 to 3 mm. of the growth. In addition, surface applications of gamma radiation by means of needles or plaques are made, with a 10 mg. half strength plaque with 2 mm. of lead screening, or its equivalent, at a distance of 1 cm. for 480 milligram hours.

2. If the lesion is of the deeper, more infiltrative type, 15 mm. in diameter and 3 to 6 mm. thick, the roentgen rays are filtered through 1 to 2 mm. of aluminum, in

doses of 800 to 1,000 r, in divided doses of 300 r every other day. In addition, two small 0.6 or 1.5 mg. interstitial needles are placed parallel to each other, 1 cm. apart, on each side of the lesion, for a total of one hundred and sixty-eight hours.

TREATMENT OF GROUP 2

The primary lesions in patients of this group are treated in much the same manner as the more infiltrated type in group 1. Palpable glands are not irradiated at the same time unless the nodes are large, hard, firm and clinically metastatic.

TREATMENT OF GROUPS 3 AND 4

In patients of groups 3 and 4 lesions from 1.5 to 3 cm. in extent are treated with interstitial needles and filtered roentgen rays in much the same manner as in groups 1 and 2. Growths larger than 3 cm., if fungating in type and infected, receive preliminary irradiation with filtered roentgen rays, 400 to 600 r daily, the factors employed being those previously mentioned, on successive days for four or five days before the implantation of the needles. The results of treatment of these larger lesions have been highly successful. Because there is a broader area treated by radiation, some degree of telangiectasia and scarring is noticeable in patients with thin, fair skin. However, the reaction induced by this method does not cause such atrophy as follows unfiltered beta radiation used in repeated doses (such as dryness, telangiectasia and ulceration). Even though such sequelae are in evidence, the lips are still moist and have a fairly normal texture, but protection from sunlight and abstinence from smoking should be maintained rigidly.

PALPABLE NODES

The total number of patients with palpable nodes was much smaller than the number of those whose nodes

were not palpable (table 9), being 48 for group 2 and 47 for group 4. Eight in whom metastatic lesions developed were not originally in group 2 or group 4. Many times when the lesions are infected on the surface swelling of the nodes is merely an inflammatory response to a long-standing infection. In the treatment of such lesions we do not feel that high voltage roentgen rays in small doses given routinely as a prophylactic

15. Regaud, C.: On Curitherapy of Epitheliomas of the Tongue and of Their Following Adenopathy, Brit. J. Radiol. 30: 361-367 (Oct.) 1925.

measure are of any value, but for glands thought to be the site of metastasis a full, adequate dose is recommended.

Since the swelling of nodes often proves to be of inflammatory origin, the routine practice of giving high voltage roentgen rays to the gland-bearing areas of

affected by metastasis were treated by block dissection; 1 had a four year cure; the other remains well after nine months.

REGRESSION OF THE PRIMARY LESION

We have not failed to cure the primary lesion in every case in which treatment has been with interstitial needles or there has been adequate radium therapy, as described, if the lesion has not been treated previously by inadequate doses of radiation. There was a total of 83 patients living and free from evidence of cancer for ten years or more and 73 for five years or more. The total treated to 1936 was 216, with 156 well at least five years, making the five year survival rate 72.2 per cent. A survey of 22 patients who died from cancer showed that more than 50 per cent were in group 4, 11 being smokers and 8 using a pipe. Two previously had been treated with escharotics (solution of potassium arsenite and nitric acid) and 1 with a hot canterly.

SYPHILIS

Association of syphilis with cancer of the lower lip has been small in our study, but results of irradiation have been equally good despite the syphilitic history. Treatment of the syphilitic infection was continued with smaller doses of arsenicals and larger amounts of the heavy metals.

COMMENT

The study of a series of 318 cases of cancer of the lip should permit drawing of certain profitable conclusions: The time we began radiation treatment falls into three definite periods in respect to the type of filtration and the amount of the dose: (1) an early period—1924 to 1932; (2) a middle period—1932 to 1935, and (3) a late period—1935 to 1941.

Early Period—1924 to 1932.—During this time we used unfiltered roentgen rays and inadequate aluminum and brass-filtered radium, thereby using mostly beta radiation. The dose was small and was repeated four or five times at intervals of six to eight weeks. The results of this treatment were satisfactory in many instances, but it was noted that doses were applied at six week intervals, sometimes over nine months' time, and that some lesions finally had to be destroyed by cautery or electrosurgical methods. The cosmetic

results were excellent on the whole, but in patients who had repeated doses of unfiltered radiation, some telangiectasia and radiodermatitis resulted. The large lesions (in patients of groups 3 and 4) were seldom entirely cured by irradiation but had to be destroyed by other methods. A total of 158 patients (table 8) were treated in the early period, with 14 deaths due to the metastasis of cancer. Twenty-one had been well for at least a year when last seen or had died from other

† We have lost contact with the patients

all patients with cancer of the lip certainly is not warranted, but patients must be selected by expert clinical judgment for the trying ordeal of heavy roentgen irradiation of the neck. No entirely satisfactory plan for dealing with metastases to the cervical nodes has yet been devised. It is felt that both surgical intervention and irradiation must be resorted to, the method that is most suitable being selected for each patient. In our series, only 27 were treated by protracted, well filtered roentgen rays to the areas of lymphatic drainage.

BLOCK DISSECTION

We feel that block dissection should not be recommended in every case of cancer of the lip but should be recommended only in selected cases. It is contraindicated, according to Duffy,¹⁶ if the primary lesion is uncontrolled, if the capsule of the node is infiltrated by carcinoma, if cross or bilateral cervical metastases are present, if distant metastases can be demonstrated or if the patient is in poor general condition.

One patient with a four year cure in our series had block dissection of a large solitary node and is now in fine general condition. Edwards¹⁷ has had encouraging results from combining radon implants in the nodes with high voltage roentgen rays. Martin⁴ has combined long needles containing a weak radium element with high voltage roentgen rays.

RESULTS OF TREATMENT

The results listed in tables 7, 8 and 9 show a high percentage of cures. This is largely because 70 per cent of the lesions seen in our clinic are 1.5 cm. or smaller in diameter, and our patients for radiation treatment are selected as carefully as those reported on by surgical groups. Patients with hopeless, advanced cancer with large, fungating growths involving the entire lip and those already showing large suppurative nodes are not given treatment with radium. If any radiation is given to such patients, it is only by heavily filtered roentgen rays, with 140 kilovolts and a filter of 6 mm. of aluminum or 170 to 200 kilovolts and copper and aluminum filters (patients so treated not included in this series). Two patients each with a single gland

16 Duffy, J. J. Conservative Procedure in Case of Cervical Lymph Nodes in Intraoral Carcinoma, *Am. J. Roentgenol* 29: 241 247 (Feb) 1933.

17 Edwards, H. G. T. Metastatic Cancer in Lymph Nodes of Neck, *South M. J.* 32: 905 911 (Sept) 1930

causes. Eighteen were in the groups with two to three year cures before they were lost track of. One hundred and five had survived for five years or more with no metastasis, contact with us being maintained during this period. The rate of five year cures for the early period was 66 per cent.

Middle Period—1932 to 1935.—This was an era in which more filtration was applied to the radium, with an increase in the length of time of treatment. One continuous well filtered application was found to be all that was necessary to produce a cure of the primary lesion. This technic, as previously described, employed the "housetop" or the "saddle" applicator in connection with roentgen therapy. The results were excellent, and the large lesions of patients in groups 2 and 4 were cured. Thus we entered into a period in which the primary lesion was almost 100 per cent curable by irradiation alone.

Late Period—1935 to 1941.—This was a continuation of the period in which the larger dose of well filtered radium was employed, but with more use of interstitial irradiation. Since the interstitial irradiation is distributed only to the labial lesion and 1 to 2 cm. of surrounding tissue, the tongue and other contiguous structures did not receive the pronounced secondary

a half after the cure of the primary lesion, and after this period contact is maintained by correspondence. The patients are also requested to make a yearly visit during the rest of their lives.

CONCLUSION

1. Three hundred and eighteen patients with cancer of the lower lip were treated by roentgen rays and radium. Twenty-two have died or now have incurable metastases (7 per cent). There was a 72.2 per cent five year survival rate.

2. Protracted radium therapy with the element well filtered has produced a higher percentage of cures than did the older technic, which employed weaker doses at short intervals.

3. Results obtained by interstitial radiation therapy in a restricted number of patients surviving five years or more revealed 95 per cent evidence of cure of the primary lesion. In a much larger number of cases of less than five years' standing, there is every indication of an equally good outcome.

117 North Broadway.

ABSTRACT OF DISCUSSION

DR. JAMES R. DRIVER, Cleveland: This paper represents a large series of cases treated over a long period. The five year results in the period from 1932 to 1941 showed 88 per cent cures as compared to 65 per cent cures in the early period, when unfiltered radiation and infrequent treatments and other forms of therapy were given. This proves the superiority of modern technics of using radiation therapy. Hardly any two workers employ identical technics in giving radiation treatment. But the use of fractional roentgen ray doses according to the Coutard principle is used by the great majority of radiologists and dermatologists today. Its superiority over older methods of using roentgen rays has been unquestionably established. The authors' experience with interstitial irradiation by the use of low intensity heavily filtered radium needles showing 95 per cent five year cures is gratifying. My associates and I have been using this form of radium therapy for over ten years and in the treatment of cancer of the lip the results have been better than by any other form of treatment. It is especially indicated in the more extensive infiltrating type of lesion. The cosmetic results are excellent and late irradiation changes are less than when roentgen rays are used. We seldom use a combination of radium and roentgen rays in the treatment of lip cancer as used by the authors. The method perhaps has the advantage of being able to administer the total combined dose in a shorter period of time. A total dose of from 4,000 to 6,000 roentgens, depending on the character of the lesion, is of chief importance and it makes little difference whether it is given by the use of radium or by the use of roentgen rays as long as it is administered according to the principle of frequent divided doses of roentgen rays or by continuous interstitial irradiation over a period of a week to ten days by the low intensity radium needles. I agree with the authors that the question of voltage and filtration depends on the size and the degree of infiltration of the lesion. As was pointed out, cancer of the lip metastasizes comparatively late in the majority of cases. Nevertheless it is in these cases that the failures occur. We believe, as the authors do, that expert surgery and radiation are indicated in all operable cases.

DR. JOHN W. SPELLMAN, Brookline, Mass.: I wish to emphasize the treatment of the regional lymph nodes rather than the control of the local disease. It is clear that no matter how effectively the disease of the lip is destroyed it will be futile if the patient succumbs later to metastatic involvement of the glands of the neck. In 1939 Taylor and Nathanson analyzed 616 cases of cancer of the lip collected from three Massachusetts hospitals with a view to determining the best method of handling the problem of the treatment of the regional lymph nodes. The pathologist found microscopic disease in 20 per cent of the cases in which no lymph nodes could be felt before operation. This fact shows conclusively

irradiation which was a drawback in the use of the "housetop" or the "saddle" applicator. In the two later periods a total of 160 patients were treated, with only 8 deaths definitely attributed to cancer at the time these statistics were compiled. Of 58 treated before 1936, 2 died from other causes before five years had elapsed, 2 were not located and 3 died of metastasis of the cancer. Fifty-one patients were living after five years, making the five year survival rate for the late period 88 per cent. One noteworthy observation has been made regarding the late period. There was a definite decrease in the size of the lesions, more of them being classified in group 1. This we feel has been due to two things: (1) the early decision to have the lesion removed, influenced by simplicity of radiation treatment without hospitalization, and (2) education concerning cancer among the laity and members of the medical profession, which has increased the chances of early diagnosis and made prompter treatment possible.

FOLLOW-UP STUDIES

The importance of a regular follow-up in cases of cancer of the lip cannot be stressed too much. All our patients are made to understand that the treatment includes observation every two months for a year and

that, if block dissection of the neck is not carried out as part of the original plan of treatment, the follow-up of this group should be careful and frequent during the first three years at least following whatever kind of local treatment is used. In the light of our present knowledge, it seems that certain general rules may be formulated to guide us in advising the safest procedure in the matter of the treatment of the cervical lymph nodes: 1. Prophylactic irradiation of the neck is never warranted, since if the glands are not involved intensive irradiation is unnecessary and even harmful, while if the glands are involved we do not believe that at present it is possible to "cure" cancer in lymph nodes by high voltage roentgen therapy. Irradiation of the neck is of course a useful palliative treatment when inoperable metastatic disease is present. 2. Routine prophylactic neck dissection is not necessary or advisable in cases in which there is a small primary lesion of low malignancy and with small or palpable lymph nodes. A close follow-up should be maintained, however, for at least three years, because a definite, if small, percentage of this group will develop cervical node involvement. If delayed neck dissection is carried out promptly after suspicion of metastasis is present, cures can still be obtained in approximately 60 per cent of these cases. 3. In cases of cancer of the lip in which regional lymph nodes measuring over 1 cm. are present after the wound has healed or the irradiation reaction has subsided, the usual suprahyoid block dissection should be carried out on the side of the lesion or on both sides if the cancer is close to the midline of the lip. In a series of neck dissections in which the nodes measured 1 cm. or more, actual involvement was found in over 60 per cent.

DR. H. J. TEMPLETON, Oakland, Calif.: There always has been argument between the dermatologist, the surgeon and the radiologist as to the best treatment of cancer of the lip, and I think that it can be partially settled by saying that a certain treatment is best in the hands of that particular individual who is most familiar with it. I have favored the use of destructive methods of treatment such as surgical excision, electrocoagulation, electrosurgery or the use of the actual cautery over radiation, although I use radiation a great deal. In 1939 I began an analysis of the cases seen in my private practice over exactly the same period as those of Drs. Lamb and Eastland, 1925 to 1939. I did not include cases seen in clinic practice. My partners and I saw a total of 113 patients with epithelioma of the lower lip. Of these 110 were men and 3 were women. Our policy in regard to biopsies has been to omit them if the lesion is typically epitheliomatous in appearance. All of our patients were seen by three dermatologists and if there was any disagreement as to the clinical diagnosis a biopsy was done; but of 52 biopsies from 102 patients 49 showed squamous cell epithelioma and 3 basal cell epithelioma. Of the 113 patients, 102 were treated by us. Earlier in our experience we treated our patients by means of extensive electrocoagulation or electrodesiccation and followed this with from 3,000 to 5,000 roentgens of unfiltered roentgen x-rays. More recently we have been inclined to omit the irradiation as we have found that our results are just as good without it. Ten of the patients whom we treated were lost track of or died from other causes and are not included in our statistics. Of the 92 whom we could follow, 88 are classified as cured for periods varying from two to five years. One patient had a recurrence after our treatment with radium but electrodesiccation was then done and the patient was known to be well three years later. One patient who had a recurrence was treated elsewhere and recovered. One patient who had a recurrence was lost track of and hence the case has to be regarded as a failure. One patient died. Out of a total of 92 patients we have 89 who are known to have recovered and remained well from two to five years. I feel that the differential diagnosis and treatment of these purely ectodermal lesions belongs particularly in the field of dermatology.

DR. JOHN H. LAMB, Oklahoma City: Dr. Driver's technic somewhat parallels ours except that he uses radium alone with equally good results. Dr. Spellman has given an excellent review of the more conservative ideas of the surgical treat-

ment, particularly with reference to routine block dissections in lip cancer. We have attempted in this review to show our end results of several years' experience in the treatment of lip cancer. There is no desire on our part to discredit other methods of treatment. In fact, we did not use radiation always alone; sometimes we use electrocoagulation and desiccation if it fails. I think Dr. Templeton's results are excellent. We feel that cancer of the lower lip is not the great problem, as it has been thought by many with the routine block sections and routine high voltage roentgen therapy to the gland bearing areas but we feel it is a disease that is amenable to certain simple forms of treatment in as high as 90 per cent of the cases.

Clinical Notes, Suggestions and New Instruments

DEVELOPMENT OF ACUTE EXFOLIATIVE DERMATITIS DURING ADMINISTRATION OF SULFATHIAZOLE

MARY WEINSTEIN, M.D., AND ALBERT H. DOMM, M.D.
PHILADELPHIA

The cutaneous manifestations of sulfathiazole intoxication have been recently described by Volini, Levitt and O'Neil.¹ They reported an incidence of 3.9 per cent in a group of 180 cases. Urticarial, erythematous, macular, papular, nodular and purpuric eruptions were encountered; the nodular lesion probably represented the advanced stage of a toxic rash and has been the most serious lesion, having been associated with a fatal outcome in a high percentage of cases.

Among 400 pneumonia patients treated with sulfathiazole reported from the Philadelphia General Hospital² the incidence of cutaneous rashes was 3.7 per cent. There were no cases of acute exfoliative dermatitis observed and to our knowledge there are no reports in the literature of this condition. It seems worth while that the following case be reported.

REPORT OF CASE

History.—R. A., a Negro aged 38, admitted March 17, 1941 to the Philadelphia General Hospital in the medical service of Dr. Edward Torrance, complained of fever and pain in the chest. For two weeks prior to admission he had a mild infection of the upper respiratory tract with weakness and malaise. On the day of admission a sharp, shooting pain in the right lower part of the chest, shortness of breath and a nonproductive cough suddenly developed. His past history was important in that he had a severe cutaneous rash about twelve years before during treatment for "bad blood," and following this attack he received no more "shots in the arm." The patient was well developed and well nourished, moderately dyspneic and acutely ill. The temperature was 101 F., the pulse rate 110, the respiratory rate 25 and the blood pressure 136 mm. of mercury systolic and 96 mm. diastolic. There was evidence of early consolidation of the right lower lobe. This was confirmed by roentgen studies on March 18. No other significant physical changes were noted.

Laboratory Examination.—A blood count revealed red cells 5,250,000 and white cells 16,900 with polymorphonuclear neutrophils 78 per cent, lymphocytes 21 per cent and monocytes 1 per

Dr. Domm is David Riesman Fellow in Medicine.

cent. The Kahn precipitation reaction was negative. The blood urea nitrogen was 17 mg. per hundred cubic centimeters; blood sugar was 120 mg. A blood culture taken on admission was negative.

The urine had a specific gravity of 1.030; it was negative for albumin and for sugar and microscopic examination of the sediment was negative. Neufeld examination of the sputum failed to yield a type with antipneumococcal serum types I to XXXIII. Culture of the sputum contained pneumococci and *Streptococcus viridans*.

Course.—Between 10:30 a. m. March 19 and 6:30 a. m. March 21, the patient received a total of 15 Gm. of sulfathiazole³ with equal amounts of sodium bicarbonate. On the morning of March 21 the temperature rose to 103 F.; the patient appeared more toxic and a diffuse macular rash was noted involving the neck, chest and arms. The diagnosis of drug rash was considered and treatment with sulfathiazole was ordered discontinued, although the patient did receive four

Eruption as it appeared twenty-four hours after onset. Courtesy of Dr. Leroy Latowsky.

additional 1 Gm. doses of the drug owing to an oversight in night orders. Within twenty-four hours the cutaneous lesions became vesicular, with exfoliation, and involved practically the entire surface of the body as shown in the illustration. There were no subjective symptoms except slight itching of the skin during the night.

The patient was seen on March 22 by Dr. Patricia Drant of the dermatology department, and a diagnosis of dermatitis medicamentosa due to sulfathiazole was considered most likely.

From March 21 to the time of his death on March 26, the patient's cutaneous lesions became progressively worse and were accompanied by a sustained fever of from 103 to 104 F. Examination of the blood on March 25 showed 3,500,000 red cells and 20,000 white cells with 68 per cent polymorphonuclear cells with a decided shift to the left, 28 per cent lymphocytes and 4 per cent monocytes. Determination of sulfathiazole in the blood at this time showed no trace of the drug.

In addition to specific treatment with sulfathiazole, the patient received, before the cutaneous lesions developed, phenobarbital

$\frac{1}{2}$ grain (0.1 Gm.) on three occasions, codeine sulfate $\frac{1}{4}$ grain (0.03 Gm.) for four doses, morphine sulfate $\frac{1}{4}$ grain (0.015 Gm.) by hypodermic injection twice and six doses of divir of terpin hydrate 1 fluidrachm (4 cc.). An ointment containing zinc oxide and boric acid was applied locally to the skin after the rash appeared.

*Autopsy.*⁴—At autopsy almost the entire cutaneous surface of the body was affected with the exception of the hands, forearms, feet and legs. Practically the entire back was denuded. The epidermis was exfoliated, leaving a brilliant red, shiny surface. This occurred in great patches, more or less extensive islands of persisting epidermis being interspersed. Nikolsky's sign was present on regions of involvement but not on the forearm, hands, feet and legs. There were no definite blebs; it appeared that the epidermis had simply been loosened from the corium.

On microscopic section the skin presented four important pathologic changes: First, there was a cleavage separation of the epidermis, unaccompanied by any frank inflammatory reaction. Reasonably, the exfoliation was a result of an accumulation of edematous fluid at the region of the basement membrane. The adjoining epidermal cells exhibited but a minor grade of edema, and it was not extreme in the corium immediately below. The epidermal cells in the prickly layer were by no means hyperplastic and the metabolism of melanin seemed to have been abrogated. Second, in connection with this edema the basal cells had undergone a peculiar inflammatory metaplasia and hyperplasia. Third, the linings of the blood vessels showed definite hyperplasia and swelling of the lining endothelium. This, occurring uniformly and diffusely throughout the entire section, speaks for a hematogenous route for the etiologic agent. Fourth, the skeletal muscle fibers at the bottom of the section were swollen and had proliferative nuclei; the transverse striations had disappeared and the fibers were not completely hyalinized. This, likewise, speaks for a general constitutional factor, whether it is the antecedent pneumonia or the sulfathiazole.

The left lung weighed 510 Gm., the right lung 750 Gm. These organs were somewhat firmer than usual in the dependent portions but no areas of consolidation were found. When the tissue was compressed a small amount of yellow gray purulent material escaped from focal points on the cut surface. Microscopic section presented only emphysema, edema and chronic passive hyperemia. The heart was dilated and hypertrophied (weight 460 Gm.) and showed a mild degree of myocardial softening and coronary sclerosis. The kidneys, liver and spleen revealed no significant changes.

COMMENT

An acute exfoliative dermatitis developed in a patient suffering from an atypical pneumonia after receiving 15 Gm sulfathiazole and he died. The abrupt onset of cutaneous involvement, increasing fever and progressive toxicity during sulfathiazole therapy for pneumonia together with the finding at postmortem of the unusual dermatologic process suggests that this case represents an instance of acute exfoliative dermatitis due to sulfathiazole. Other than an overwhelming toxemia resulting from the widespread and severe involvement of the skin, no satisfactory cause of death was found. Neither clinically nor microscopically did this dermatologic process resemble anything with which we are familiar except Ritter's disease. This, which is also known as dermatitis exfoliativa neonatorum, concerns infants exclusively and usually involves the face and there are not the degenerative changes in the capillaries which were exhibited in this case. It is of significance that this patient experienced a cutaneous rash in 1929 following intravenous therapy, presumably from arsphenamine, for "bad blood."

Certainly the potential danger of sulfathiazole dermatitis should be kept in mind with the first appearance of cutaneous lesions. Withdrawal of the drug and forcing of fluids at the earliest sign of cutaneous manifestations constitute the safest procedures, although, as demonstrated in this case, the outcome may still be fatal.

3. The sulfathiazole used in this hospital was free of phenobarbital contamination.

4. The autopsy was performed by Dr. Earl Keller.

COLLAPSE FOLLOWING PARENTERAL ADMINISTRATION
OF SOLUTION OF THIAMINE HYDROCHLORIDE

LEON SCHIFF, M.D., CINCINNATI

The following experience is being reported because, as far as I am aware, a similar case has not been recorded and because it deals with a therapeutic substance which is frequently used at present.

A school teacher aged 45 had been suffering with a mild form of Raynaud's disease since 1932 and with a progressive hypertrophic arthritis of the lumbar spine and sacro-iliac regions since 1933. In April 1940 she had a severe attack of right-sided sciatica for which, among other measures, injections of thiamine hydrochloride were started. A total of thirty-six intramuscular injections of 25 mg. was given between April 16 and July 10, with two different commercial preparations. She vomited twenty minutes and one hour after her eighteenth injection on May 21, 1940.

No more thiamine hydrochloride was given until August 6, at which time the first preparation used was resumed. By August 16 she had received six injections with either nausea or vomiting following four of them. Administration of a third preparation was begun August 24 and continued to September 7, for a total of five injections. This preparation was resumed October 7, and ten injections were given up to December 20.

On December 28, about one or two minutes after receiving her injection of thiamine hydrochloride into the buttocks (from a 5 cc. vial from which she had had six previous injections), the patient became nauseated and vomited. A thin, colorless fluid issued from her nose; she voided involuntarily and collapsed. Her skin was covered with a cold perspiration. She was pulseless and had ceased breathing, and her heart sounds were inaudible. She was placed on a table in shock position and surrounded with covers. Artificial respiration was started, and 1 cc. of solution of epinephrine hydrochloride was injected intravenously. She was also given 1 cc. of epinephrine subcutaneously and $7\frac{1}{2}$ grains (0.5 Gm.) of caffeine with sodium benzoate intramuscularly. Her blood pressure could not be obtained at first. About half an hour later her pulse was palpable and her blood pressure was 110 systolic and 70 diastolic. On being questioned following her recovery, she stated that she had had short bouts of sneezing a short time after the last three or four injections of the thiamine hydrochloride.

On Jan. 2, 1941, an intradermal scratch test done with two of the commercial preparations resulted in a definite white wheal surrounded by an area of hyperemia which itched and reached its maximum in from fifteen to twenty minutes, at which time slight nausea and coughing occurred. On January 25, scratch tests done with 0.5 per cent solution of chlorobutanol, used as a preservative in the first preparation, and with a solution of hydroxyquinoline sulfate, which was used as a preservative in the last preparation, were negative. A similar test done with an aqueous solution of thiamine hydrochloride was positive. There was a white wheal 1 cm. in diameter surrounded by an area of erythema about 3 cm. in diameter, reaching a maximum size in twenty minutes. The intradermal test repeated on February 1 with an aqueous solution of thiamine hydrochloride was again positive. A passive transfer test performed by Dr. Albert Zoss on February 27 was negative.

This experience strongly suggests that the shock suffered by the patient may have been due to sensitivity to solution of thiamine hydrochloride. In view of the rapidity with which the reaction occurred, it is assumed that some of the thiamine hydrochloride must have been administered intravenously on the occasion of the last injection.

Special Article

GLANDULAR PHYSIOLOGY AND
THERAPY

ACTIVATED STEROLS IN THE TREAT-
MENT OF PARATHYROID
INSUFFICIENCY

A REVIEW

FRANKLIN C. McLEAN, Ph.D., M.D.
CHICAGO

This special article is published under the auspices of the Council on Pharmacy and Chemistry. It is one of a series which will be published in book form as the second edition of Glandular Physiology and Therapy. The opinions expressed in this article are those of the author and do not necessarily represent the views of the Council.—Ed.

It is now well established that certain products derived from activated ergosterol are highly effective in increasing the concentration of calcium in the blood and in relieving the symptoms of parathyroid insufficiency. It appears, from some years of accumulated clinical experience, that these products may be administered over a considerable time with reasonable safety, provided proper precautions are observed, and that their prolonged use is attended neither by injury to the patient nor by the development of tolerance.

The subject of the management of hypoparathyroidism with the activated sterols assumes especial importance because of the fact that substitution therapy, in the form of administration of solution of parathyroid, is virtually limited to rather acute conditions, in which the treatment needs to be continued for days or weeks rather than months.¹ Not only is no tolerance to the activated sterols developed but they also have the decided advantage that the preferable method of administration is by mouth. On the other hand, the action of the sterols is somewhat delayed, so that for the relief of acute parathyroid tetany solution of parathyroid may be indispensable.

Reviews of the use and limitations of solution of parathyroid are available.² This review presents the principles underlying the use of the activated sterols in the treatment of parathyroid insufficiency, current knowledge concerning the mode of their action, a consideration of their toxicity and a brief summary of clinical experience with the preparations at present available for this purpose. Because of the unwarranted implication in the current literature that the beneficial effects of one of the derivatives of irradiated ergosterol (dihydrotachysterol) in hypoparathyroidism are specific for that substance, it will be necessary to emphasize the evidence to the contrary. The conclusion is reached that similar, if not identical, effects may be obtained from several of the activation products of ergosterol and cholesterol and that there is no satisfactory evidence that the therapeutic effects of dihydrotachysterol are superior to those of vitamin D when the latter is given in comparable doses. This review does not consider the use of vitamin D products for purposes other than to regulate the concentration of calcium in the plasma.

CHEMISTRY AND PREPARATIONS

The distinction between the antirachitic action of the irradiation products of ergosterol and those actions which are responsible for the toxicity of certain of these products was first clearly drawn by Holtz and Schreiber³ in 1930. They were unable to make a preparation which was antirachitic but nontoxic but by appropriate chemical treatment could destroy most of the antirachitic action while retaining and actually increasing the toxic effects. As a reference to the dominating symptoms of the toxic actions of irradiated ergosterol—hypercalcemia and pathologic calcification in the soft tissues—they named the principle responsible for these effects the calcinosefaktor. Holtz and his co-workers were then responsible for the further study of this factor, here called the "calcemic principle," and eventually⁴ for its introduction into clinical use in the form of dihydrotachysterol, originally known and frequently referred to in the literature as A. T. 10 (antitetanic preparation 10).

TABLE 1.—Vitamin D Activity and Toxic Borderline Doses of Various Derivatives of Irradiated Sterols

	Vitamin D Activity, I. U. per Mg.	Toxic Borderline Dose,* Mg.
Calciferol.....	40,000	0.05-0.07-0.125 (Morris and McLean, ³⁷ Holtz, Gürsching and Kraut, ⁴⁰ Shohl and Farber ⁴⁴)
Dihydrotachysterol		
Crystalline, pure.....	200 ⁵	0.010 ⁶
Commercial, A. T. 10.....	80-100 (Harnapp, G. O.: Monatschr. f. Kinderh. 63: 262, 1935. Shohl and Farber ⁴⁴)	0.025 ⁶
Toxisterol.....	Little or no anti- rachitic activity	0.025 ⁴⁰
Tachysterol.....	Little or no anti- rachitic activity	0.200 ⁴⁰
Lumisterol.....	Little or no anti- rachitic activity	Not toxic

* All the data on toxic borderline doses are obtained from observations on mice, by the method described,¹⁰ except for the observations of Morris and McLean³⁷ and of Shohl and Farber,⁴⁴ which were obtained on rats by comparison with dihydrotachysterol.

The action of the calcemic principle is nonspecific⁵ and is shared by vitamin D₂, vitamin D₃, 22-dihydro-vitamin D₂, dihydrovitamin D₂ II, tachysterol, dihydrotachysterol, 22-dihydrotachysterol and probably also toxisterol. Of these, only vitamin D₂, in the forms of crystalline calciferol and of viosterol, and dihydrotachysterol have received sufficient investigation and clinical trial to warrant a review of their usefulness in the treatment of hypoparathyroidism. Toxisterol appears to have toxic actions qualitatively different from those of the other substances considered.⁶

The chemistry of the activated sterols has been reviewed by Bills.⁷ Irradiation of ergosterol leads to the following chain of reactions: ergosterol→lumisterol→tachysterol→calciferol (vitamin D₂). Further irradiation leads to formation of toxisterol and of the supra-sterols I and II. More radiant energy is required to decompose calciferol than to produce it, so that when

irradiation is not unduly prolonged calciferol is the chief product.

Calciferol is vitamin D₂ and is available in pure crystalline form. The international unit (I. U.) of vitamin D, which is quantitatively the same as the U. S. P. unit, is equivalent to 0.000,025 mg., or 0.025 micrograms of crystalline calciferol. One milligram of calciferol is equivalent to 40,000 international or U. S. P. units of vitamin D. Vitamin D₃ is activated 7-dehydrocholesterol and is the chief form in which vitamin D is present in fish liver oils.

Viosterol is the nonproprietary name adopted by the Council on Pharmacy and Chemistry of the American Medical Association⁸ for all acceptable preparations of irradiated ergosterol. Under the best conditions of preparation it is composed of approximately 50 per cent of calciferol, with lumisterol and tachysterol accounting for most of the remainder.⁷ It is standardized in terms of its vitamin D activity, so that the content of lumisterol and tachysterol, which have little or no antirachitic effect, are not taken into account. In ordinary use, for the prevention or treatment of rickets, the amounts of these substances administered are negligible, but when doses sufficient to produce the calcemic effect of vitamin D are given tachysterol will contribute appreciably to this effect. Lumisterol has not been shown to have any toxic, or calcemic, effect.

The chemistry of dihydrotachysterol, including the method of preparation of a pure crystalline product, has been described in detail by von Werder.⁵ Dihydrotachysterol differs from calciferol only in the saturation of a double bond, but this difference is sufficient for the disappearance of all but a small fraction of the antirachitic action and for a decided enhancement of toxicity. Dihydrotachysterol is formed when tachysterol, one of the irradiation products of ergosterol, is treated with sodium and propyl alcohol. It is available only in the form of an oily solution, described as containing 5 mg. of the basic substance per cubic centimeter, of which approximately 2 mg. is pure dihydrotachysterol.⁵

Holtz and his co-workers¹⁰ introduced a biologic method by which the available preparation of dihydrotachysterol is standardized. A "toxic borderline dose" is the amount which when given in ten single daily doses over a period of thirteen days to a series of 8 male mice weighing from 16 to 18 Gm. will produce a loss in weight of more than 2.5 Gm. or death in at least 50 per cent of the animals.⁹ Table 1 summarizes the available information concerning antirachitic activity and toxicity of the preparations considered in this review.

DOSAGE AND TOXICITY

It will be shown that much confusion over the use of vitamin D in the management of hypoparathyroidism has arisen from the fact that there are two distinct dosage ranges for this substance. The prophylactic and curative range for the antirachitic effect, with which this review is not concerned, is ordinarily 700 to 1,000 international units a day.¹¹ The dosage necessary for the elevation of a subnormal serum calcium and its maintenance at a normal level is commonly 60,000 to 200,000 international units daily and may be even

higher over short periods. Administration of dihydrotachysterol has been completely divorced from the system of units by which vitamin D preparations are standardized and, being standardized only in terms of its calcemic principle, is free from the confusion that exists in the case of vitamin D. Since the calcemic principle, common to both vitamin D and dihydrotachysterol, is identical with the factor responsible for the toxic manifestations of overdosage with both sterols, and since the desirable therapeutic effect depends on the administration of subtoxic doses of these substances, the question of dosage will here be considered in relation to toxicity.

The effectiveness of the calcemic principle is affected by the degree of parathyroid insufficiency, by the intake of calcium and phosphorus, by the female hormone, and perhaps by other physiologic variables. For this reason there are no absolute standards of dosages necessary to produce therapeutic or toxic effects. The available information, however, does not permit of any quantitative treatment of the subjects of dosage and toxicity in relation to the other variable factors concerned.

Initial Dosage.—Treatment of parathyroid insufficiency is commonly initiated with relatively large doses of the activated sterols, followed by smaller maintenance doses. Initial and maintenance doses will be considered separately.

Relatively large doses of dihydrotachysterol have been used and recommended for initiating treatment of acute attacks of hypoparathyroidism. More common practice, in chronic parathyroid insufficiency, is to initiate treatment with from 1 to 4 cc. daily of the oily solution (5 to 20 mg. of the basic substance). As it will be shown that at least 10 mg. of calciferol is required for a calcemic action equivalent to that of the 5 mg. of basic substance contained in 1 cc. of the solution of dihydrotachysterol, a corresponding daily dose of calciferol would be 10 to 40 mg., or 400,000 to 1,600,000 international units of vitamin D.

While these doses have the appearance of being enormous, owing to the system of units employed, there is little evidence of harmful effects of such doses, administered over relatively short periods. Spies and Hanzal¹² gave as much as 18,000,000 international units of vitamin D a day, in the form of viosterol, for from nine to twenty-five days to patients about to die of disease. They observed no symptoms referable to the medication, except for a rise in the serum calcium level to as high as 16.6 mg. per hundred cubic centimeters, and at autopsy found no pathologic calcification or other changes which they could attribute to the vitamin D. Steck and his associates¹³ administered as much as 3,000,000 international units of vitamin D a day for fifteen days to a normal subject without evidence of disturbance of any kind. Single doses of vitamin D, commonly about 600,000 international units, are now frequently administered to infants in the so-called Stosstherapie of rickets, the literature having been reviewed by Vollmer¹⁴ and by Reed, Struck and Steck.¹⁵ Cowdry and Scott¹⁶ reported giving viosterol

to monkeys, of less than 3 Kg. body weight, in doses amounting to 27,600,000 international units of vitamin D within two hundred hours. They made no mention of clinical symptoms. Goormaghtigh and Handovsky¹⁷ reported lethal effects on 4 dogs following single doses of 13 to 20 mg. (520,000-800,000 international units) of calciferol per kilogram of body weight. Five other dogs, given from 2.9 to 8 mg. per kilogram, survived.

Much of the earlier literature on the toxicity of vitamin D preparations must be discarded, owing to the wide use of a preparation of irradiated ergosterol with low vitamin D and high toxisterol content.¹⁸ In the literature of the past few years I have been able to find no report of serious toxic effects from large initial doses of dihydrotachysterol and only one case following large doses of vitamin D over a relatively short period of time. A case is reported¹⁹ of an obese physician aged 74 with generalized arteriosclerosis who took by mistake 2,300,000 international units of vitamin D, in the form of a concentrated solution of viosterol, daily for eighteen days, or a total of more than 40,000,000 international units. Nausea, anorexia, weakness, increased thirst and polyuria developed and finally he went into coma and died.

Maintenance Doses.—The dosage of the activated sterols necessary to maintain the serum calcium within normal limits, and to avoid the symptoms and sequelae of hypoparathyroidism, is dependent on the subject and certain physiologic variables, more particularly the degree of parathyroid deficiency present and the intake of calcium and phosphorus, and varies within wide limits. The extreme limits for dihydrotachysterol are given as from 0.15 to 1.0 cc. (0.75 to 5 mg. of the basic substance) daily. More commonly 0.3 to 0.5 cc. a day is needed. An equivalent dose of calciferol would be from 1.5 to 10 mg. (60,000-400,000 international units) a day for the extreme limits, and 3 to 5 mg. (120,000-200,000 international units) for the more commonly prescribed dose. The same variability, but within approximately the same limits, in the amounts of calciferol actually found to be necessary for maintenance doses is reviewed later.

Reports of accidental poisoning with vitamin D preparations, even when administered over long periods, have been rare in late years, most of the literature on the toxicity of these preparations having come from the deliberate administration of large doses in conditions other than hypoparathyroidism. In this connection Steck, Deutsch, Reed and Struck²⁰ have made an exhaustive investigation of the toxicity of vitamin D. For the most part they used concentrated preparations of viosterol, but comparable results were obtained with crystalline calciferol. They conclude that both human subjects and dogs generally survive administration of 20,000 international units of vitamin D per kilogram of body weight daily for indefinite periods without intoxication. Out of 773 human subjects receiving more than 100,000 international units daily over variable periods, 63 showed toxic symptoms, but with no deaths and with no effects from which recovery did not occur. Steinberg²⁰ administered a preparation of vitamin D, usually in doses of 160,000 international units a day, for periods of several weeks to one and one-half years,

factor was completely independent of whether the vitamin D activity in the preparations used was destroyed by heating or reduction or not. The non-specificity of the calcemic effect has again been emphasized by von Werder,⁵ and the method used for standardization of dihydrotachysterol, which depends on the toxicity in mice, is in no way capable of distinguishing between the qualitative actions of the various sterols.

Holtz has published no experiments with a preparation identifiable with dihydrotachysterol as now distributed. However, von Brand, Holtz and Putschlar³³ compared the actions of various preparations, standardized in terms of their toxicity in mice, and of solution of parathyroid, using a large number of animals of various species. They found numerous differences; in the nature of the pathologic calcification produced, in the curve of the rise and fall of the serum calcium and in the relative susceptibility of the various species to the two substances. They consequently assumed a difference in the mode of action of the sterols and of solution of parathyroid but found, in spite of these differences, that in experimental tetany in dogs, resulting from a deprivation of parathyroid tissue, the action of the parathyroid hormone could be completely substituted for by the calcinosefaktor. In a subsequent paper Holtz, Gürschling and Kraut⁴⁰ confirmed these results by observations in man.

Albright, Bloomberg, Drake and Sulkowitch³⁰ have reported studies of the actions of dihydrotachysterol and of calciferol which have been much quoted. They made comparative studies of the actions of these two substances on the calcium and phosphorus metabolism of 3 patients with parathyroid insufficiency, and a similar study of the action of solution of parathyroid in 1 of these cases. They found that the two sterols have the same two actions of increasing calcium absorption from the gastrointestinal tract and of increasing phosphorus excretion in the urine, the ratio of the latter action to the former being greater with dihydrotachysterol. They noted also that the action of calciferol was slower in coming on and lasted longer than that of dihydrotachysterol. Albright, Sulkowitch and Bloomberg⁴¹ reported similar results in a case of vitamin D-resistant rickets, with the exception that dihydrotachysterol did not cause as marked a rise in excretion of urinary phosphorus. In none of these studies was consideration given to the possibility of a direct effect of the preparations on bone. They gave calciferol at the most in amounts equal to those given of dihydrotachysterol, while for strictly comparable effects the ratio should have been at least 2 to 1.³⁷

Himsworth and Maizels⁴² treated a patient with congenital hypoparathyroidism for six years, mainly with calciferol. The dosage was maintained, during the greater part of the time, at 12.5 mg. (500,000 international units) a week, with excellent results. During an interim period of ten months dihydrotachysterol was substituted for calciferol. It was effective in controlling the tetany, but the impression of the authors was that "in this patient vitamin D₂ produced a more stable state than did A. T. 10." They used up to 6 cc. a week of

the dihydrotachysterol preparation, which should have been equivalent to 60 mg. of calciferol, or nearly five times the dosage of the latter actually employed. Poer⁴³ has compared dihydrotachysterol and calciferol in the treatment of 11 cases of post-thyroidectomy hypocalcemic tetany. He found that the two substances are equally effective in controlling the symptoms of hypoparathyroidism and in maintaining the serum calcium level near the normal. His usual daily maintenance doses were 1.25 mg. (50,000 international units) of calciferol and 0.3 cc. (1.5 mg.) of dihydrotachysterol. It has not been found by others that this amount of calciferol is usually adequate for a maintenance dose.

Morris and McLean³⁷ have studied the actions of these two substances in rats. They compared the loss of weight, the mortality, the effects on the bones, as observed histologically, and the onset, distribution and intensity of pathologic calcification in the soft tissues. When given in a ratio of 2.24 mg. of calciferol to 1 mg. of dihydrotachysterol, the loss of weight of litter mates fed the two substances became indistinguishable, and the effects with reference to the other criteria enumerated were also comparable. Using the same dosage ratio, they administered the two substances to dogs. The serum calcium curves showed no significant differences, both substances exhibiting the same ability to raise the serum calcium. From these experiments it is concluded that calciferol must be administered in the ratio of at least 2 mg. to 1 mg. of the basic substance of the commercially available solution of dihydrotachysterol to obtain the same calcemic effect. Others have reported a still higher ratio for the doses necessary to produce comparable toxic effects in mice⁴⁰ and in rats⁴⁴ (table 1).

Shohl⁶ has made comparative studies of the pathologic changes induced in rats by toxic doses of calciferol and of dihydrotachysterol and has found that the two produce similar effects. Both caused striking lesions in the kidneys and blood vessels. Calcification was produced in the gastric mucosa. Both caused demineralization of the bones and hypercalcification at the zone of provisional calcification. Neither led to necrosis of the liver produced by an early preparation of irradiated ergosterol,⁴⁵ and now believed to be due to its high content of toxisterol.¹⁸

The comparative studies quoted indicate a qualitative difference between the actions of toxisterol on the one hand and vitamin D and dihydrotachysterol on the other. They fail, however, to disclose any difference in the actions of the two latter substances on which a preference for either one or the other may be based. Further carefully controlled comparative studies, in both clinical and experimental hypoparathyroidism, are required before it can be finally said that calciferol and dihydrotachysterol are of equal value in the management of this condition or that either has advantages over the other.

CLINICAL EXPERIENCE WITH DIHYDROTACHYSTEROL

Of a large number of reports on the use of dihydrotachysterol in hypoparathyroidism, virtually all are unreservedly favorable. In nearly every report the possibility of overdosage is discussed and the necessary

precautions are described, but there are few instances of actual toxic manifestations. In a discussion of the first eight years' experience with the preparation, Holtz²⁸ stated that long-continued administration is without harmful effects and without development of tolerance, that no lasting damage is done if a temporary hypercalcemia of about 15 mg. per hundred cubic centimeters is induced by overdosage and that the danger of toxic effects was overemphasized in the earlier publications. He reported that an occasional patient refractory to dihydrotachysterol was seen. This report of Holtz reflects the general tenor of the large German clinical literature, which will not be reviewed in detail here.

Dihydrotachysterol appears to have been first used in this country by Arnold and Blum,⁴⁶ who reported favorably on its effectiveness in 2 cases of postoperative and 1 of idiopathic tetany. Swinton⁴⁷ reported favorably on 6 cases of postoperative tetany. MacBryde,⁴⁸ from observation of its effects in 6 cases of chronic hypoparathyroidism and 1 of idiopathic tetany, stated that it was the only therapeutic measure in his experience to yield excellent results in treatment of chronic tetany. Pickhardt and Bernhard⁴⁹ reported 2 cases of postoperative tetany. Albright, Bloomberg, Drake and Sulkowitch⁵⁰ made extensive metabolic studies of 3 cases, concluding that dihydrotachysterol "is a most efficacious therapeutic agent in the treatment of hypoparathyroidism." Rose and Sunderman²⁵ reported 5 cases of hypoparathyroid deficiency, their observations including determinations of calcium balance, total and diffusible serum calcium, serum protein and inorganic serum phosphorus before and during administration of dihydrotachysterol. They concluded that this preparation is highly effective in increasing the concentration of calcium in the serum and in relieving the symptoms of parathyroid deficiency. In 1 of their cases, following 2 cc. of dihydrotachysterol daily for twenty-six days, severe symptoms of intoxication appeared, including vertigo, tinnitus, thirst, polyuria, nausea and abdominal cramps, with a rise of the serum calcium to 15.7 mg. per hundred cubic centimeters.

Numerous other reports have appeared,⁵⁰ the tone of all being favorable and all emphasizing the advantages

of dihydrotachysterol over solution of parathyroid in the management of the hypocalcemia associated with parathyroid insufficiency. The reports are virtually unanimous with respect to the details of management. An initial dosage of 1 to 4 cc. daily is commonly continued until the serum calcium level rises to 9 to 10 mg. per hundred cubic centimeters and the symptoms of tetany subside. Following this, individualization of the maintenance dose becomes necessary, and this dose is determined by trial and error. The maintenance dose varies between 0.15 and 1 cc. a day and is more commonly 0.3 to 0.5 cc., but owing to the duration of the action of the substance the required dosage need not be given more often than twice a week. The rise of serum calcium may occur without any addition of calcium to the dietary intake, but the same effect can be obtained with considerably lower dosage of the sterol if the calcium intake is supplemented with from 12 to 20 Gm. daily of a calcium salt, commonly the lactate, chloride or gluconate. The desirability of a low intake of phosphorus is also emphasized.

The most acceptable criterion for regulation of the dosage is frequent observation of the serum calcium level, but the Sulkowitch test, introduced by Albright,⁵¹ appears to be reliable, especially if checked occasionally with determinations of the serum calcium. The test gives a simple and rapid means of detecting or excluding excessive excretion of calcium in the urine, from which the presence or absence of hypercalcemia may be inferred. It has the great advantage that it may be applied daily, or even more frequently, by the patient himself, in much the same way that diabetic patients learn to perform rough quantitative tests for sugar in their urine. According to Goormaghtigh and Handovsky,¹⁷ a serum calcium concentration of 13 mg. per hundred cubic centimeters should be cause for alarm, as it is the prelude to massive calcium excretion, tubular distention and subsequent glomerular regression.

Holtz and Rossmann⁵² found that the dose of dihydrotachysterol had to be increased as much as six times during the latter half of pregnancy, and this has been confirmed by Curtis,²⁶ who gave 3 cc. daily during the last four months of pregnancy, or a dose equivalent to 30 mg. (1,200,000 international units) of calciferol a day. Holtz and Rossmann⁵² also found that the dosage of dihydrotachysterol may have to be increased during menstruation and that the effectiveness of a given dose is reduced by the administration of estradiol benzoate. On the other hand, the requirement for dihydrotachysterol is decreased after roentgen castration in women.⁵³

Holtz and Kramer⁵⁴ have found that larger doses are required during periods of activity, nervous strain and menstruation, and Arnold and Blum⁴⁶ have also noted the increased requirement when the patient becomes very active. The variations that are required in dosage with pregnancy and with administration of estrogen are reminiscent of the early observations of the influence of

estrus, pregnancy and lactation on the course of experimental parathyroid tetany.⁵⁵

Hypercalcemia and other toxic manifestations of overdosage of dihydrotachysterol are usually managed by withdrawal of the medication, including the calcium added to the intake, by rest in bed and by increasing the intake of fluid. Holtz and Rossmann⁵³ suggested the administration of large doses of estrogens to combat toxicity, and Seiferth and Kolb⁵⁶ reported that the vitamin B complex and vitamin C have a far reaching inhibitory influence on the toxic effects of dihydrotachysterol. They reported that vitamin A increases the toxicity of this sterol, but Morgan, Shimotori and Hendricks⁵⁷ stated that a low intake of vitamin A leads to an increase in the damaging effects of toxic doses of vitamin D. None of these antagonistic actions appear to have been given adequate clinical trial in actual poisoning with the activated sterols.

In judging the usefulness of an activated sterol over a long period, consideration should be given to its ability to prevent or to relieve the complications or sequelae of parathyroid insufficiency, as well as to its ability to raise the serum calcium level. Of these, the most troublesome is the occurrence of cataracts. Klemens⁵⁸ described the opacities in the lens characteristic of hypoparathyroidism, as seen with the aid of the slit lamp, and stated that a presumptive diagnosis of the nature of the condition can usually be made from the changes in the eye alone. He stated that administration of dihydrotachysterol prevents this condition and as a rule arrests its progress if it has already begun before the preparation is administered. Because there is a widespread impression to the contrary, he emphasizes his statement that no clearing up of already formed opacities of the lens can be expected from administration of dihydrotachysterol. Schmidt-La Baume⁵⁹ has reviewed the use of dihydrotachysterol in dermatologic conditions associated with hypocalcemia, more especially in impetigo herpetiformis.

Certain cerebral and psychic symptoms are frequently associated with hypoparathyroidism. They include restlessness, irritability, depression, headache and occasional epileptiform convulsions, of central origin. These and other manifestations referable to the central nervous system are said to be relieved promptly by treatment with dihydrotachysterol. Barr, MacBryde and Sanders⁶⁰ reported a case of idiopathic hypocalcemic tetany, associated with increased intracranial pressure and papilledema, together with beginning opacities of the lens. The case responded promptly to treatment with dihydrotachysterol, and the authors suggested that edematous changes in the brain or meninges may occur in hypoparathyroidism more frequently than is recognized and that this factor may be of importance in producing cerebral and psychic

manifestations of tetany. Eaton and Haines⁶¹ reported 3 cases of parathyroid insufficiency with symmetrical cerebral calcification, in 1 of which the symptoms were relieved by administration of dihydrotachysterol. They regard symmetrical cerebral calcification, mental deterioration and convulsions as concomitant but not necessarily interdependent cerebral symptoms of hypoparathyroidism.

Dihydrotachysterol has been little used in infantile tetany, and Chu and Sung⁶² regarded it as of doubtful advantage in view of the common association of this condition with vitamin D deficiency and rickets. Bloxson,⁶³ however, has reported that hypocalcemic tetany in an infant, believed to be of parathyroid origin, was controlled by this sterol, but, it will be noted, in doses large enough to have an appreciable vitamin D activity. Eisenstein⁶⁴ has reported a case of tetany in an adult, regarded as "secondary to prolonged intestinal dysfunction," relieved by the administration of dihydrotachysterol. The preparation has also been used in other conditions, even more remote from disorders of the parathyroids. Its use in the treatment of otosclerosis, introduced by Seiferth⁶⁵ on the basis of reported slight reduction of serum calcium values in this condition, is stated by Schütz⁶⁶ to be without theoretical justification or empirical usefulness.

The American literature is still inadequate with respect to reports of the progress of patients kept under observation and under treatment with dihydrotachysterol over extended periods. It would be desirable to have further reports on some of the cases in which treatment was instituted some years ago.

VITAMIN D IN CLINICAL HYPOPARATHYROIDISM

It will be recalled, from the foregoing discussion of dosage and toxicity, that vitamin D ordinarily has no effect on the serum calcium level unless administered in a daily dosage range of 60,000 to 200,000 international units or even higher and that consequently no effect in the treatment of hypoparathyroidism, comparable to the beneficial effects reported from the administration of dihydrotachysterol, can be expected unless vitamin D is administered at these levels. Irradiated ergosterol was administered in these amounts in the treatment of clinical hypoparathyroidism as early as 1928 with good results,⁶⁷ but in most instances the dosage of vitamin D employed has been much below that which is necessary to produce the effects under discussion. The early literature has been reviewed by Boothby and Davis,⁶⁸ and many of the unfavorable or equivocal results quoted by them can be clearly traced to insufficient dosage. Except for purposes of comparison, this review will refer only to clinical experience with adequate doses of preparations of vitamin D.

Bauer, Marble and Claflin⁶⁹ reported in 1932 on 3 cases of hypoparathyroidism in which irradiated ergosterol was administered in doses of 5 mg. a day. The preparation was that responsible for much of the confusion concerning toxicity of vitamin D. Beneficial results were observed in all 3 cases, but only when the calcium intake was adequate. Reed and Seed⁷⁰ reported in 1933 on the treatment of 10 cases of parathyroid tetany in which viosterol was administered in doses up to 920,000 international units a day over periods of several days. Reed, Struck and Steck⁷¹ reported on the subsequent history of these patients, together with 5 more whose treatment was initiated after publication of the original report. In 1939 all but 5 of the 15 patients in the series had been able to discontinue vitamin D therapy without recurrence of tetany. Of these 5, 4 had continued the treatment for six or seven years but were able to secure freedom from tetany on approximately one tenth of the dosage required at first, and without recourse to calcium.

Freyberg, Grant and Robb⁷² emphasized the necessity for large doses if satisfactory results from the administration of vitamin D in hypoparathyroidism are to be expected. They gave as much as 200,000 international units of vitamin D as viosterol a day, with definite benefits, but most of the time used from 20,000 to 40,000 units. Stacey²² gave up to 8 mg. (320,000 international units) of calciferol a day, with favorable results. Himsforth and Maizels⁴² reported a case in which calciferol was given for six years, with excellent results. For the greater part of this time the dosage was maintained at 12.5 mg. (500,000 international units) a week. During one period vitamin D₃ was substituted for calciferol (vitamin D₂), with identical results. Farquharson⁷² undertook to find the smallest daily dose of irradiated ergosterol that would relieve the symptoms of 2 patients suffering from severe chronic postoperative tetany refractory to other forms of treatment. One of these patients became free from tetany and remained well for four and one-half years with a daily dose of 94,000 international units of vitamin D. In another patient, with the same dose, favorable results were obtained, the symptoms of tetany recurring when the medication was discontinued. Klatskin⁷³ made a careful study of 2 cases of chronic parathyroid tetany, giving calciferol in doses up to 7.5 mg. (300,000 international units) a day, without the occurrence of toxic manifestations. He recommended calciferol "as a valuable therapeutic agent in cases of chronic parathyroid tetany which do not respond to high calcium-low phosphorus diets and in whom satisfactory transplants of parathyroid gland are not possible." Poer⁴³ has used calciferol, in doses of 1.25 mg. (50,000 international units) a day, with effects comparable to those seen with dihydrotachysterol. Anderson and Lyall⁷⁴ found that the minimum dose of vitamin D necessary

to raise the serum calcium to a normal level in parathyroid deficiency appears to lie between 30,000 and 40,000 international units a day.

Of especial interest, in view of the conclusions in this review, are the reports in which vitamin D preparations are compared unfavorably with dihydrotachysterol. Table 2 summarizes data derived from five such reports⁷⁵ and includes the dosage of dihydrotachysterol required to produce the desired effect and the maximum dosage of vitamin D which failed to produce this effect. The latter is compared with the dosage of vitamin D calculated to be equivalent in "calcemic principle" with the dosage of dihydrotachysterol.

It is at once apparent from table 2 that the chief source of the unfavorable comparisons made by the authors of these reports is a misapprehension as to what constitute doses of vitamin D comparable to those of dihydrotachysterol. In three of the five reports the doses of vitamin D are 10,000 international units a day or less, or within an entirely different dosage range from that required to raise the serum calcium level. MacBryde⁴⁸ used up to 40,000 international units a day, or doses on the borderline of those found by others to be effective in the treatment of parathyroid insuf-

TABLE 2.—Summary of Reports Favorable to Dihydrotachysterol and Unfavorable to Vitamin D

Authors	Dihydrotachysterol: Daily Dose Giving Favorable Effect, Cc.	Vitamin D	
		Equivalent to Dihydro- tachysterol, Units	Maximum Actually Given, Units
Margolis and Krause ⁷⁵	1.0	400,000	1,700
Ryan ⁷⁵	0.5	200,000	3,000
Curtis ⁷⁶	1.0	400,000	10,000
MacBryde ⁴⁸	0.25-1.0	100,000-400,000	40,000
Adams ⁷⁶	2.0	800,000	120,000

iciency, but gave no further details. In the single case reported by Adams⁷⁶ he gave 120,000 international units of vitamin D daily for two weeks during subacute tetany five weeks after thyroidectomy, or an amount which ordinarily should have been sufficient to produce the calcemic effect. After two weeks of this treatment the symptoms continued unabated and the serum calcium remained at about 5 mg. per hundred cubic centimeters. After two weeks of treatment with 2 cc. of dihydrotachysterol (equivalent in calcemic principle to 800,000 international units of vitamin D) daily, the serum calcium rose only to 6.8 mg. per hundred cubic centimeters, but the symptoms were relieved. Two and one-half months later the patient was discharged on a maintenance dose of 1 cc. of dihydrotachysterol twice a week. It appears that during the acute or subacute stage of her tetany this patient was resistant to both vitamin D and dihydrotachysterol and that sufficient dosage only of the latter was given.

It would appear that there is no reason to attribute a higher degree of specificity or a lesser likelihood of toxicity to dihydrotachysterol than to vitamin D.

That doses of the latter sufficient to produce effects comparable to those of dihydrotachysterol can be given with at least the same degree of safety, provided the same precautions are observed, is established. There is needed, however, a larger volume of clinical experience with vitamin D comparable to that accumulated for dihydrotachysterol.

COMMENT

The present review emphasizes my point of view that the burden of proof is on those who would maintain that dihydrotachysterol is a better or safer agent in the treatment of hypoparathyroidism than is vitamin D. This statement does not in any way detract from the proved effectiveness, usefulness and comparative safety of dihydrotachysterol. It seeks merely, and on the basis of the available evidence, to put vitamin D in the same category with respect to the same physiologic actions and therapeutic usefulness.

The present favor in which dihydrotachysterol finds itself, in comparison with the disfavor or relative indifference to vitamin D, appears to have arisen from the following considerations: First, the earlier trials of vitamin D were mainly with inadequate dosage, and comparisons are still made between antirachitic doses of vitamin D and full calcemic doses of dihydrotachysterol. Second, the early experience with toxic preparations of irradiated ergosterol, resulting from their high content of toxisterol, led to a fear of poisoning with overdoses of vitamin D, a fear which has not been supported by the experience of the past few years. Third, the standardization of vitamin D products in terms of antirachitic units leads to the expression of dosages adequate for the management of hypoparathyroidism in terms of tens or hundreds of thousands or even of millions of units. With a background of fear of overdosage, the physician faces the psychologic barrier of having to prescribe what appear to him to be enormous, and frequently described as "massive," doses of a toxic preparation.

All these handicaps have been removed in the case of dihydrotachysterol. Although its toxic, and therapeutically effective, principle appears to be identical with that of vitamin D, it was introduced without the same fear of toxic effects. Its dosages are expressed in the innocuous terms of cubic centimeters, and even when "toxic borderline doses" are referred to the dosage is in hundreds rather than in millions of units. Moreover, it was introduced for one purpose only and has been given publicity only for this purpose. Without any direct claim to this effect having been made, the impression has become widespread that its action is specific, and in the current literature it is even referred to as "a new form of parathyroid hormone."

It is my belief, from the evidence available at present, that preparations of vitamin D are as effective and as free from danger as is dihydrotachysterol. More clinical experience is needed, and a system of standardization and of dosages free from the present handicaps to the use of vitamin D for the purposes here discussed is required. For pure vitamin D₂, or calciferol, dosage should be

expressed in milligrams. Preparations of irradiated ergosterol should be standardized in terms of their content of the calcinosefektor, which will include the activity of the tachysterol content. The method of Holtz, Laquer, Kreitmair and Moll¹⁰ is probably suitable for this purpose. The physiologic activity, in terms of the toxic factor, should then be referred back to pure calciferol rather than to arbitrary "toxic borderline units." A rough calculation, assuming that irradiated ergosterol contains about 25 per cent tachysterol, indicates that average viosterol should have about 16 per cent more calcemic activity than is indicated by its content of vitamin D₂.

It now seems that the dangers of administration of both dihydrotachysterol and of vitamin D have been somewhat exaggerated. They must be administered with care and with the proper precautions, but the immediate dangers are apparently no greater than in the case of insulin. Frequent determinations of serum calcium are desirable not only during the initial stages but also after maintenance doses have been arrived at. The Sulkowitch test,¹¹ by which the excretion of calcium into the urine is observed by a simple and roughly quantitative method, may serve to avoid the necessity for frequent examinations of the blood.

That prolonged administration of these products will lead to chronic injury in man has not been shown, nor is it clear that the danger does not exist. The effects on the arteries and arterioles of dogs have been referred to. In any case the possibility of such danger must, in cases of hypocalcemia resulting from hypoparathyroidism, be weighed against the very probable occurrence of opacities of the lens, and perhaps of other sequelae of this condition. At present the evidence is that the risk of injury from the therapeutic agent is far less than that from the condition which it is intended to combat.

Finally, I wish to enter a plea for the abandonment of the term "hypervitaminosis D." Not only is the term misleading and nondescriptive but it is also a deterrent to the legitimate and desirable use of vitamin D products in the treatment of hypocalcemia. The term "vitamin D," without further qualification, refers solely to the antirachitic activity of the activated sterols, although "vitamin D₂" and "vitamin D₃" are now used to refer to specific chemical substances. Since the toxic effects from administration of vitamin D products are shared with other products having little or no vitamin D activity, it is clear that the characteristics of the sterol molecule responsible for its antirachitic activity are not those responsible for the toxic effects. There is no evidence that overdosage with the antirachitic factor per se leads to any undesirable effects. For these reasons the toxic actions of the activated sterols should be separated from their antirachitic activity in terminology as they are in fact.

SUMMARY

1. A number of substances derived from activation products of ergosterol and cholesterol have the effect of raising the serum calcium when administered in sufficiently large doses, this effect resulting from a combination of the mobilization of calcium from the bones and an increase in absorption from the gastrointestinal tract. Of these, only vitamin D₂ (calciferol)

77. Slaughter, E. C.: Experimental Hyperparathyroidism and Osteosclerosis, *Ann. Otol., Rhin. & Laryng.* 49: 130-140 (March) 1940.

and dihydrotachysterol (also known as A. T. 10) have been extensively used clinically.

2. Because of this effect on the serum calcium, here called the "calcemic effect," both of these substances are highly effective in increasing the concentration of calcium in the blood and in relieving the symptoms resulting from hypocalcemia in cases of insufficiency of the parathyroid glands. The substances may be administered by mouth over considerable periods of time and with reasonable safety, provided proper precautions are observed. Their prolonged use is attended neither by injury to the patient nor by the development of tolerance.

3. When the two substances are administered in comparable doses their effects are qualitatively and quantitatively similar, if not identical. It has not been shown that either is superior to the other in the management of hypoparathyroidism. Previous unsatisfactory experience with vitamin D products has been due either to insufficient dosage, in which case no beneficial results were obtained, or to the effects of a widely used preparation containing the toxic products of overirradiation.

4. The dangers of the toxic effects of these substances in the preparations now available, while real, have been somewhat overemphasized. Frequent determinations of serum calcium are desirable both to determine that the desired elevation has been obtained and to avoid the dangers of hypercalcemia. The Sulkowitch test, by which the excretion of calcium into the urine is observed and which the patient himself learns to perform, serves to permit close observation and at the same time to reduce the frequency of the necessary blood examinations.

5. While the possibility of chronic injury resulting from prolonged administration of these substances has not been excluded, such injury has not been demonstrated. At present the evidence is that the risk of injury from the therapeutic agent is far less than that from the condition it is intended to combat.

6. The "calcemic principle" responsible for the elevation of serum calcium and for the toxic actions of the activated sterols has been dissociated from the antirachitic activity of certain of these sterols. In the case of vitamin D the antirachitic activity and the calcemic action are apparent in widely separated dosage ranges. Confusion as to dosage and the expression of calcemic doses in terms of tens or hundreds of thousands of units have been handicaps to the use of vitamin D in the management of hypocalcemia.

7. It is urged that these handicaps be removed by the expression of dosages for the calcemic effect in terms of weight of calciferol. In the case of viosterol, which contains other substances with the same action but not accounted for in the standardization of this preparation in terms of antirachitic activity, the calcemic effect should be determined by biologic standardization and referred back to pure calciferol.

8. The term "hypervitaminosis D" should be abandoned. The term is misleading and non-descriptive and is a deterrent to the legitimate and desirable use of vitamin D products in the treatment of hypocalcemia.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
HOWARD A. CARTER, Secretary.

BURDICK SU-4 ELECTROSURGICAL UNIT ACCEPTABLE

Manufacturer: The Burdick Corporation, Milton, Wis.

The Burdick SU-4 Electrosurgical Unit provides a means of applying the various technics used in surgical diathermy. Two currents, one of which is from a spark gap high frequency generator and the other from a vacuum type oscillator, are supplied. For cutting, the tube current alone or a blend of the two currents is used, and the current from the spark gap generator is used alone for coagulation. Standard accessories furnished with the unit include an electrode handle with cork and attachment plug, silver indifferent electrode, small and large size ball coagulation electrodes, needle for cutting or coagulation, tungsten knife blade and straight knife blade for dissection, set of five long needles and ball electrodes for coagulation, and an instrument rack.

Mounted on a steel chassis, the unit is contained in a steel cabinet having a white enamel finish. A lower section of the cabinet provides storage space for the foot switch, cords and accessories. A removable instrument tray is supplied with the apparatus.

The standard type spark gap circuit has a high voltage condenser with heat dissipating cast aluminum mountings connected across the transformer secondary. A WL-460 tube is used in the Hartley circuit with parallel feed plate supply, using alternating current for its anode voltage, and is isolated from the spark gap oscillator and blending circuit by variable magnetic coupling. Five line voltage adjustments are provided by a line transformer.

Burdick SU-4 Electrosurgical Unit.

The blending circuit contains a coil capacity coupled to the spark gap circuit and magnetically coupled to the tube circuit, being common to these two generating circuits. The patient circuit is capacity coupled to this coil. Since the two generating circuits operate without appreciable influence on each other and either generator will feed the patient outlet alone, the output blended current is the sum of their individual outputs. The parallel connection of circuits is a feature; according to the firm, with this connection the ratio of between the spark gap oscillator component in the blended current remains constant with varying patient impedance and current. A separate circuit and outlet provided for large electrode coagulation disconnects the spark gap circuit from the blending circuit.

Three controls on the operating panel consist of a six position master switch, a dissection power control regulating the amount of current from the spark gap generator. Each component of the blended current can be separately controlled. The foot switch has two pedals; the one marked "Coagulation" turns on the spark gap generator. When the master switch is set on "Blended Current," the "Dissection" pedal of the foot switch turns on the two generators simultaneously, producing the blended cutting current.

The unit was investigated clinically by the Council and was found to give satisfactory service.

The Council voted to accept the Burdick SU-4 Electrosurgical Unit for inclusion on its list of accepted devices.

Areteus Anticipated Kraepelin.—Arctacus (30-90 A. D.), a clinician of the second century, described the auras of epilepsy, differentiated senile and involutional states, and seems to have been the first to propose the clinical concept of "circular psychoses." He anticipated Kraepelin by eighteen hundred years in his manic-depressive theories.—Lewis, Nolan D. C.: *A Short History of Psychiatric Achievement*, New York, W. W. Norton & Co., Inc., 1941.

ALLEGED TYPHOID ULTRAVIRUS

Among the basic medical researches interrupted by the war, Magrassi's¹ introductory studies of the toxicity or pathogenicity of the dissociable "Vi antigen" of *Eberthella typhosa* are of peculiar interest. Ordinary laboratory strains of the typhoid bacillus differ from freshly isolated cultures, as was demonstrated nearly fifty years ago by Sanarelli.² He found freshly isolated bacilli highly toxic for guinea pigs and mice and incapable of agglutination with antityphoid serum. Both the toxicity and the inagglutinability, however, are rapidly decreased and eventually lost on subculture. Sanarelli concluded that toxicity, virulence or pathogenicity are nonessential characters of the typhoid bacillus, which may be gained or lost by proper environmental exposure. The typhoid bacillus, according to this view, was a nonpathogenic mechanical carrier of some unknown autocatalytic toxic enzyme in about the same way that it is now conceived to carry bacteriophage.

Sanarelli's discredited theory was reformulated by Felix and Pitt³ about forty years later. They found that in addition to the well recognized flagellar and somatic antigens a third antigen is present in freshly isolated strains of *E. typhosa*. This third antigen gradually decreases in amount and eventually disappears on subculture, its decrease being parallel with loss of toxicity or virulence. Felix and Pitt therefore suggest that this third antigen should be known as the "virulence factor" or "Vi antigen."

Numerous investigators have shown that this Vi antigen is readily dissociable from the typhoid bacillus. By incubating a freshly isolated saline suspension of *E. typhosa* for four hours, the Vi factor is set free in the suspension fluid and may be separated from the formed elements by high speed centrifugation or Chamberland filtration. The highly toxic filtrate thus obtained is

readily inactivated by heating to 60 C. for thirty minutes.

Friedberger⁴ had said that a dissociable toxic factor plays a role in clinical typhoid. Aqueous extracts of the organs of patients dying of typhoid were found to be highly toxic for guinea pigs. The brains of guinea pigs killed during the acute febrile reaction to this tissue toxin will transfer the toxic symptoms to normal guinea pigs, and brain to brain transfer of typhoid "endotoxin" could be continued indefinitely without appreciable loss of virulence. Friedberger concluded from this serial transfer that the etiologic factor in typhoid is a double "entity," a microscopically visible and culturable typhoid bacillus supplemented by an invisible, noncultivable autocatalytic "cryptic antigen." In today's terminology this "cryptic" antigen would be classed as an ultravirus.

This "binomial" theory of typhoid was received with universal skepticism twenty years ago. Following the development of modern theories of synergic virus-bacterial infections (e. g. swine influenza), however, experimental verification of the Friedberger concept was undertaken by Italian investigators. Sanarelli and Alessandrini,⁵ for example, attempted to disprove the theory by showing that Friedberger's alleged synergic ultravirus is nothing more than an invisible phase of *E. typhosa*. In this they were unsuccessful, as regeneration of the typhoid bacilli was not possible from the invisible toxic filtrate.

Friedberger's synergic theory was therefore tentatively accepted as a working hypothesis by the Italian investigators. Magrassi and his co-workers¹ of the Institute for General Clinical Medicine, University of Rome, confirmed Friedberger's basic experiments. Substituting baby rabbits for the more resistant guinea pigs of previous experiments, they found that a Chamberland filtrate of partially autolyzed virulent *E. typhosa* is highly toxic. Injected intraperitoneally or intravenously in 4 to 8 cc. doses of standard dilution (200 million *E. typhosa* organisms per cubic centimeter) the Vi antigen produces diarrhea, muscular weakness and rapid loss of weight with an occasional death within twenty-four hours. Most of the rabbits, however, soon recover from the initial symptoms following injection and remain apparently normal for from eight to twelve days. At the end of this latent period a recurrence of the diarrheal symptoms develops. The rabbits usually lose a third of their original weight before death, which usually occurs in from two to three days. An occasional animal may survive as long as ten to thirty days. Magrassi found that the initial toxic reaction could be avoided by reducing the dose of the filtrate to 0.5 cc. injected intracerebrally. The terminal fatal emaciating

diarrhea after a latent period of eight to twelve days is the only toxic manifestation by this method of injection.

On necropsy a great majority of the intracerebrally injected rabbits yielded heart blood, brain, spleen and liver that were bacteriologically sterile, colon bacilli being the only occasional contaminant. Confirming Friedberger's discredited data, Magrassi found that 0.5 cc. of a 10 per cent aqueous extract of the brains at necropsy would reproduce the fatal emaciating diarrhea if injected intracerebrally into normal rabbits and that this brain to brain transmission of the autocatalytic toxic factor could be continued for at least six generations, the highest number of passages attempted by the time of the interruption of his work.

The possibility that this apparently successful transfer of typhoid encephalitis might be due to some latent neurotrophic virus was eliminated by the Italian investigators, who did numerous control tests. Heat inactivated Vi antigen, autolysates of avirulent strains of *E. typhosa* and 10 per cent extracts of normal rabbit brains would not reproduce the disease. Magrassi found also that the heart blood of the rabbits which were subjected to such passage almost invariably contained typhoid agglutinins of relatively high titer (e. g. 1:400 to 1:12,800), a specific antibody production that could hardly be expected from an unknown contaminant.

A second constant finding in the rabbits with typhoid encephalitis was a massive overgrowth of colon bacilli in the small intestine. This led to the belief that the hypothetical typhoid ultravirus is capable of "activating" or "energizing" normal intestinal saprophytes, conferring on them a distinct toxicity or pathogenicity. This overgrowth led the Italian investigators to believe that the terminal emaciating diarrhea in typhoid encephalitis is due to "Vi activation" of colon bacilli.

Attempts to measure the size of this hypothetical typhoid ultravirus, its cultivation on modern virulologic mediums and its possible infectivity on intranasal instillation were not completed at the time of the discontinuation of this work. Magrassi, however, feels justified in concluding from his interrupted data that a highly pathogenic ultravirus can be dissociated from freshly isolated virulent typhoid bacilli, that this dissociated virus is capable of independent multiplication in the brain and other tissues of baby rabbits, and that so grown the ultravirus is capable of directly or indirectly "activating" the normal intestinal flora, conferring a lethal toxicity on it.

Friedberger's discredited synergic theory of typhoid infection has therefore apparently received sufficient experimental confirmation to warrant serious reconsideration.

THE PATIENT COMES FIRST

Hardly half a century has passed since hospitals for the treatment of private patients were first established. Previously hospitals were maintained for the benefit of those who were destitute. Obviously such hospitals depended for their support on public appropriations or on voluntary gifts. Services of the physician were freely contributed without thought of compensation. Asepsis, which made possible elective operations, and a radical change in our domestic economy, initiated fundamental changes in the situation. Now all classes of society have become accustomed to resort to the hospital both for diagnosis and for treatment in minor as well as in major illnesses. The hospital today frequently derives a part, sometimes all, of its income from paying patients. Increasingly hospitals sell their services to the self-supporting members of society.

This transformation of the economic status of the hospital has not been achieved without evidences of maladjustment, as emphasized by Dr. Miles Atkinson¹ in the *Atlantic Monthly*. Amidst the complexities of organization and administration, he says, we have lost sight of the fact that hospitals exist primarily for the benefit of the sick. The doctor occupies the second place in importance. Without him and the patient there would be no need for the hospital. Building and equipment are needed to aid the physician to apply his knowledge and skill in the treatment of the sick. The hospital and its administrators, then, take only the third place in the medical economy, a fact too often overlooked, so that the hospital organization becomes an end in itself, to the detriment of patient and staff. The present crisis, according to Dr. Atkinson, is due at least in part to the lavish expenditures of the postwar era, which have left us a legacy of costly buildings, heavy mortgages, needless equipment and unnecessary personnel. The notion that aggregations of institutions would simplify management or effect economies has proved to be a delusion. "A hospital is not a factory." Patients cannot be treated *en masse*. One of the evils of unduly expanded institutions is excessive specialization.

Private hospitals in recent years, by reason of diminishing income from endowment and from subscriptions, have resorted to the policy of charging in the lower income brackets whatever the traffic will bear. Unforeseen consequences of this policy have been the exploitation of the patient and of the doctor as well. Too often the roentgen ray department and laboratories have been operated for profit. The same may be true of the pharmacy. In either case the patient and the public suffer, as well as the physician and pharmacist.

Dr. Atkinson concludes that hospitals are abusing their position. Nobody cavils at the work they do, but many cavil at the means they adopt to do it. The hospitals, he believes, are in a parlous state, and something very soon will have to be done about it.

¹ Atkinson, Miles: *The Patient Comes First*, *Atlantic Monthly*, August 1941.

Current Comment

ESSENTIAL FRUCTOSURIA

Essential fructosuria is a rare anomaly of metabolism, apparently harmless but sometimes mistaken for diabetes. It is characterized by inability to utilize fructose completely. The disturbance is manifested by the presence of fructose in the urine in amounts proportional to the quantity of sugar ingested. Because of its rarity it has been difficult to speculate convincingly concerning the etiology. Now however Lasker,¹ by adding 7 new cases to the literature and analyzing them as well as the 40 previously reported, is enabled to demonstrate a familial occurrence. Although the evidence for inheritance of this disturbance is not yet conclusive, its occurrence in sibs, its nonoccurrence in the parents and offspring of persons with fructosuria, and the frequency of consanguinity of parents of such persons all offer evidence to indicate that fructosuria is inherited as a mendelian recessive characteristic. Final confirmation of this theory may be long in coming, however, since additional evidence can be accumulated only slowly because of its rarity.

BIOTIN IN TUMOR TISSUE

The search for biochemical differences between normal and tumor tissue is being continued by investigators with the hope that the presence of an abnormally low or unusually high concentration of a particular substance in tumor tissue may be a clue to some aberration in the metabolism of living tissue which is responsible for the neoplasm. Of particular interest are substances of vitamin or enzyme nature which, as components of catalytic systems, exert a profound regulatory effect on the rate of metabolic processes. Biotin, or "vitamin H," is one of the more recently studied of these compounds and is said to exert a catalytic influence in minute concentrations. This substance is essential for the normal function of many micro-organisms and also for higher animals. In a recent preliminary communication, West and Woglom¹ report observations on the relative abundance of this growth factor in various tissues, including certain tumor tissues. In the case of every type of tumor studied, with one exception, the biotin content of the tumor was found to be distinctly higher than the concentration of this vitamin in control normal tissue of the same type. In rats with primary carcinoma of the liver induced by feeding butter yellow, the biotin level of the liver adjacent to the neoplasms was found to be normal, while the carcinomas themselves, unlike the other tumors analyzed, were distinctly lower in their biotin content. In every case studied the biotin level of the tumor deviated sharply from the normal adult values in the same direction as that of the corre-

sponding embryo tissues. This relationship appears to be a difference in metabolism shared by tumor and embryo rather than a change common to all rapidly dividing tissue, as the biotin content of rat liver vigorously regenerating after partial hepatectomy or of the pregnant human uterus was not found to differ from that of the same tissues in a nonhyperplastic state. It has been further suggested by Laurence² that both malignant cells and micro-organisms which have been found associated with the observed cases of spontaneous recession of tumors require excess biotin for their metabolic activities. If this hypothesis is correct, the spontaneous recessions might be explained as the direct result of biotin deficiency brought about by the avidin-like action of the micro-organisms, thus depriving the malignant cells of a factor vital for their continued existence. (Avidin is a special constituent from raw egg white, which has a biotin-binding capacity *in vitro*.) Whether or not this theory can be confirmed, the discoveries already made have opened a new line of investigation on the physiology of tumors.

ORAL ANDROGENIC THERAPY

Physicians have been recently advised of the availability of an androgen which is far more potent, orally, than the testicular hormone testosterone. This substance, methyl testosterone, has been shown to be as effective orally as one third to one fourth the amount of injected testosterone propionate necessary for adequate replacement therapy in eunuchoid or castrate animals. The biochemists who first prepared this material have indeed made a noteworthy contribution to endocrinology. Nevertheless, physicians should not readily accept the extravagant therapeutic claims made by the firms which are marketing this substance (Schering, Roche-Organon and Ciba) or the urge to prescribe methyl testosterone as an economical and practical form of medication. The Council on Pharmacy and Chemistry has declared, in a report on the status of testosterone propionate, that final judgment of androgenic therapy must await additional evidence and that the only worthwhile indication for this therapy at present seems to be its application in the treatment of eunuchoidism or castration in the male. The other indications for androgenic therapy should be subjected to further investigation. In the light of this report, the indications for methyl testosterone should be scrutinized carefully. Furthermore, relatively large amounts of methyl testosterone are essential for effective therapy. On the basis of available reports, it is necessary to administer 50 to 100 mg. of this material daily for complete replacement therapy in the castrate. Physicians should therefore contemplate the economic aspects of administering such doses over the appropriate period of time. Actually reports dealing with the use of methyl testosterone in such conditions as menstrual disorders, painful breasts, menopausal symptoms and prostatic adenoma are meager and quite inconclusive.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

THE PREHABILITATION OF REGISTRANTS

V. A UNIVERSITY PROGRAM TO PREPARE STUDENTS FOR MILITARY SERVICE

RUTH E. BOYNTON, M.D.

AND

HAROLD S. DIEHL, M.D.

MINNEAPOLIS

The administration of the University of Minnesota believes that higher educational institutions have not only an opportunity but also an obligation to prepare their students for the parts which they will be called on to play in the national defense program. University departments concerned with health, physical fitness and recreation are in a position to utilize their resources in equipment, buildings and personnel to render a special service to the men who will be selected for military training. With this in mind, during the spring quarter of 1941 an experimental program was planned and carried out for the prehabilitation of university students registered under the Selective Training law.

This program consisted of (1) registration of all men in the university to determine their status in regard to Selective Service, (2) a complete medical examination according to the physical standards of the Selective Service Act, (3) an examination to determine the physical strength and endurance of these students, (4) a written examination to give information of the recreational interests and skills of these men, (5) a comprehensive examination in personal hygiene and public sanitation, with special attention to requirements of army life, and (6) the development of a program based on information gained in these tests which would enable all students needing remedial work or special classes to obtain them.

REGISTRATION

The only part of this program which was compulsory was the registration of all male students in the university. A card was sent to each male student asking for information on age, whether registered for Selective Service, and if so registered his classification (if any), his Selective Service numbers, and whether he expected an early or late call for Selective Service. Such information cards were sent to over nine thousand male students. Of this number 46 per cent replied that they had registered for Selective Service. In certain colleges with older students the percentage registered for Selective Service was naturally much higher. For example, in the Graduate School 92 per cent of the students were registered, in Medicine 87 per cent and in Dentistry 76 per cent, whereas in the College of Science, Literature and the Arts only 26 per cent of students were of draft age.

Of those students registered for Selective Service, one thousand, two hundred and sixty-eight either had

low call numbers or signified their wish to participate in the prehabilitation program, although they did not expect an early call.

MEDICAL EXAMINATIONS

The medical examinations were given during the spring vacation and in the evening of the first week of the spring quarter to make it possible for students to have examinations without interfering with their class work. The examinations were carried out according to the physical examination standards set up under the Selective Service Act. On completion of the examination each student was classified according to Selective Service standards as follows: class I-A, fit for general military service; class I-B, fit for limited military service; class 4-F, unfit for any military service.

Nine hundred and twenty-nine students were given medical examinations. The classifications of these according to the physical standards of the Selective Service Act were as follows: class I-A, 599, or 64 per cent; class I-B, 199, or 21 per cent; class 4, 79, or 8.5 per cent; classification deferred pending further study, 52, or 6.5 per cent. Over one half of the 52 whose classification was deferred will be put in class I-A. Approximately 30 to 33 per cent of the group will finally be classified either as class I-B or class 4. This percentage is approximately the same as that found among the men in this vicinity already inducted into military service under the Selective Service Act.

Table 1 lists the major causes for restricted classification with the percentage rejected for unlimited service for each cause. Although the total percentage of university students classified as I-B or class 4 is approximately the same as for the draftees who have been examined by the Selective Service examiners, the causes for restricted classification differ from the findings of the draftees examined in Minnesota. A report on the physical examination of 17,337 Minnesota registrants for Selective Service who were examined during January 1941 is available. Of this number 33 per cent were put in class I-B or class 4. A comparison of the defects which caused disqualification for these draftees with the defects found in University of Minnesota students is given in table 2.

The two striking differences between the groups are the high percentage of college students given restricted classifications because of visual defects and the low percentage of college students given restricted classifications because of defective teeth. The large majority of students with restricted classifications because of visual defects were myopic. All cases so classified had the myopia corrected by glasses. The 7 per cent of the group who were restricted in classification because of underdevelopment were those who were either underweight or under the required height or whose chest measurements did not meet the standards set under the Selective Service regulations. Many of the young men in this group could reach the standards set by a proper program of diet, rest and exercise.

It is worthy of note that the large majority of university students who were given restricted classifications because of physical defects had defects of a character which are not correctible so far as army service is concerned. All students whose physical defects are remediable are being followed up and arrangements are being

TABLE 1—*Causes for Restricted Classification*

	Class I B—Total No., 199	
	Number	Per Cent
Defects of vision	114	57.7
Orthopedic defects	22	11.1
Underdevelopment	20	10.0
Hearing loss	9	4.6
Teeth	7	3.5
Hernia	7	3.5
All other	20	10.0

	Class 4—Total No., 79	
	Number	Per Cent
Defects of vision	39	49.4
Orthopedic defects	9	11.4
Ear defects	8	10.1
Duodenal ulcer	7	8.9
Heart disease	6	7.6
All other	10	12.6

made for the correction of these defects through the student's private physician or through the Health Service.

PHYSICAL STRENGTH OR FITNESS TESTS

The physical fitness tests were given by the Department of Physical Education for Men. These tests were designed to give an estimate of the "present condition" of the men relative to their ability to sustain physical effort and to resist fatigue and at the same time to test their native ability for certain types of activities. The tests as given consisted of:

1. The number of times the subject could "push up" on the parallel bars.
2. The number of times he could pull up on the horizontal bar ("chin").
3. The height (in inches) that he could jump (measured from standing reach to jumping reach).
4. The time it took him to run 440 yards.
5. His ability to swim

The combination of the first three tests of physical fitness has been found to correlate significantly with physical ability and is a relatively good indication of physical development. It is the opinion of the Department of Physical Education and quite generally of the physical education profession that a combination of tests, such as those included in this battery, gives a fairly good indication of the subject's physical condition and ability.

These tests were given to seven hundred and sixty-one university men in the group who were registered for Selective Service. The results of the tests showed that this group of students was approximately 8 per cent below the norm for college men. It seems evident that probably the majority of college men could profit from some program which would "condition" the muscles, thereby making the transition from college life to army service easier for the individual.

SPORTS KNOWLEDGE TEST

A sports knowledge test, which was given to 805 men, consisted of objective tests of ten items on each of fourteen sports. The sports selected were those which are likely to be available to the men who are serving in

the various branches of the service. It was the opinion of the Department of Physical Education that a fundamental knowledge of several sports would contribute to the student's ability to use wisely his leisure hours and would therefore be helpful in his adjustment to life in the cantonment. This opinion is based on the fact that, if a person has some knowledge of and skill in an activity, he is more likely to participate in that activity if the opportunity presents itself. Although no norms are available for the tests given, in general it was found that these university men have a fairly adequate knowledge of sports in general but are somewhat lacking in knowledge and skills in individual sports—that is, those sports which require only one or two participants.

HEALTH INFORMATION TESTS

The health information test on personal and public health and hygiene was given to eight hundred and seventeen men in this group. Out of a possible score of 188, the all-college median was 117, with a range from 106 to 146.

When the results of this test were divided according to colleges, it was evident that students in colleges which include health information courses in their curriculums attained the highest scores. The results of this test led us to recommend that all colleges require some course in health education for all students.

On completion of all these tests each student was given a report on his individual results and advised of the facilities which the university had to offer him so that he might make up any deficiencies found.

The information on the number of students who have availed themselves of these facilities on a voluntary basis is not complete, but from the information available it appears that relatively few students have changed their programs to include special work in physical education or personal hygiene. One reason for this is that this plan was started after students had completed registration for the spring quarter and it was difficult for them to make adjustments at that time. It seems evident, however, that if a university is to aid young men in preparing themselves, so far as health and physical fitness are concerned, for army service, a compulsory program must be adopted.

TABLE 2—*Comparison of Defects*

	University Students Total No., 218	Minnesota Draftees Examined in January 1911 Total No., 2,003
Defects of vision	55.0%	10.0%
Orthopedic defects	11.0%	11.0%
Underdevelopment	7.0%	0.5%
Ear defects	8.0%	3.6%
Teeth	3.0%	2.8%
Hernia	2.5%	1.5%
Heart disease	2.2%	0.0%
Tuberculosis	0.0%	1.1%
Venerable diseases	0.0%	1.1%

* Percentage of total defects

As a result of this trial program in the spring of 1941, the Administrative Committee of the University Senate recommended that, for the fall quarter of the school year 1941-1942,

1. A medical examination be offered again on an optional basis.

2. The faculties of each college of the university consider the desirability of requiring each student to take an introductory course in personal and public health for credit.

3. The physical fitness tests which were given as a part of the spring quarter program be included as a required part of

the medical examination which is compulsory for all incoming students. If this should be done, all students who were found to need "conditioning" could be encouraged to take a carefully planned, individual, remedial program in physical education.

4. In view of the importance of national physical fitness, the colleges of the university institute a required program in physical education with credit.

TRAINING OF VOLUNTEER NURSES' AIDES

The U. S. Director of Civilian Defense, Mayor F. H. LaGuardia, announces the training of one hundred thousand volunteer nurses' aides during the next twelve months, in collaboration with the American National Red Cross and the major hospitals of the country. The program is in preparation for a great expansion in hospital beds which may be required during the national emergency.

The growing deficiency in hospital personnel is now being met in part through the training of large numbers of paid subsidiary hospital workers by the NYA, WPA and other agencies. The training program for volunteer nurses' aides is designed to expand the effectiveness of the trained nurse in hospitals, clinics and field nursing services by supplying her with intelligent assistants who can work under her direction.

The curriculum of instruction has been prepared by the Medical Division of the Office of Civilian Defense, the American National Red Cross and the Federal Security Agency. Eligibility is limited to women between the ages of 18 and 50 who have had at least a high school education or its equivalent and who are physically fit. The course will provide eighty hours of intensive instruction in a period of seven weeks. The first half of the course will be given in the local Red Cross chapter house in collaboration with local hospitals and nursing organizations. This will constitute the probationary period and will require two hours of instruction daily on five days a week for four weeks.

The second half of the course will consist of supervised practice in a hospital which has been designated by the Office of Civilian Defense and the Red Cross as a training center. The American National Red Cross will assist the hospital to provide competent instructors and nursing supervisors.

Those who complete the course will be enrolled in the Volunteer Nurses Aide Corps of the American Red Cross with the assurance that they will play an important role in civilian defense. They will retain their membership in the corps only as long as they continue to render adequate service during the period of the national emergency. This is defined as one hundred and fifty hours of volunteer service in a hospital, clinic or field nursing organization in at least one three month period in each calendar year.

The Office of Civilian Defense and the American National Red Cross will provide for this continuing service by arrangement with local hospitals and field nursing agencies. For this purpose the Red Cross will maintain a placement bureau, which will allocate volunteer nurses' aides to the following types of nursing service: hospitals and clinics, visiting nurse (home visiting) agencies, health departments, school health services and industrial hygiene clinics.

By serving in this manner as assistants to qualified nurses, their training will be continued. In the event of sudden emergencies during a period of national crisis they will then be immediately available for reassignment to hospital or field duty by the Office of Civilian Defense. There will be opportunity for some to serve as members of the mobile medical field units which are being organized in hospitals along both seaboard and in industrial centers in the interior, according to plans announced this week by the U. S. Office of Civilian Defense.

Volunteer nurses' aides will wear the uniforms and insignia of civilian defense. The new insignia for nurses' aides will be a red cross within the triangle and circle of the Office of Civilian Defense, indicating that the aide was enrolled and trained by the Red Cross to serve in civilian defense.

Applicants may enroll at the Red Cross chapter house, and the course will begin in each locality as hospital arrangements are completed.

In addition, a committee has been appointed to prepare for distribution to students and advisers a booklet of information giving systematic guidance and advice on opportunities in courses and activities at the university in the fields of health, physical education and recreation for both selectees and the general student body.

OVERSEAS MEDICAL SUPPLIES ARRIVE SAFELY

The Medical and Surgical Relief Committee of America, 420 Lexington Avenue, New York City, announces in its annual report that supplies valued at \$251,698.08 have been shipped overseas during the last year and a half and that every consignment shipped was safely delivered to its destination. While the committee was organized in 1940 to aid Great Britain, the committee has expanded its purpose to provide medical and surgical supplies also for people in China, the Free French, the Free Greeks, the inhabitants of Iceland and the Royal Norwegians on British convoys. The original New York City committee has been augmented by three hundred subcommittees throughout the country and yet the operating expenses have been kept down to 7 per cent of the total receipts, according to Mrs. Rogers Balcom, executive chairman of the committee. Surgical instruments still head the list of requests received from overseas. There is a great demand also for sulfanilamide and its derivatives, for quinine, for vitamins, for tryparsamide and for antitoxins.

RELIEF COMMITTEE SELLS EMBLEMS

The Medical and Surgical Relief Committee of America opened the sale of a new emblem during the annual session of the American Medical Association in June. The emblem has the form of a modified caduceus combined with a sword of mercy and sells for \$1. At the ceremony in Cleveland Miss Theodate Johnson, national vice chairman, presented emblems to Drs. Nathan B. Van Etten, New York, then President, and Frank H. Lahey, Boston, now President of the American Medical Association.

During its first year the committee shipped to Great Britain and the allied countries supplies valued at \$191,198. The year's operating expenses amounted to 6½ per cent of the total receipts, a result attributed to voluntary service on the part of physicians and nurses.

It was announced on June 30 that \$10,000 worth of supplies shipped to the Free French in Iceland had arrived safely. Thirteen cases of supplies were recently shipped to relief agencies in Cairo, Egypt.

RESERVE OFFICERS WITH THE SECOND, TENTH AND ELEVENTH INFANTRY

The following medical reserve officers were recently on duty with the regiments indicated in the Sixth Corps Area:

2D INFANTRY

APPELMAN, Howard B., Captain	SCHUTZMAN, Benjamin M., 1st
LEAVITT, Samuel S., 1st Lieut.	Lieut.
MILLARD, Allen L., Major.	SINTZEL, Alois R., Captain.
NELSON, Charles A., 1st Lieut.	STARSIK, Casimir R., 1st Lieut.
RUBIN, Simon S., Captain.	PEARLMAN, Maurice D., 1st
ROMANSKI, Arthur F., 1st	Lieut.
SOROCK, Milton L., 1st Lieut.	PISZCZEK, Edward A., 1st Lieut.
	PRUDOWSKY, Harry, 1st Lieut.
	WOOD, Cordelle A., Major.

10TH INFANTRY

BROWNSTEIN, Stanley, 1st	NEBINGER, Rankin A., Captain.
Lieut.	STORER, William R., 1st Lieut.
DILORETO, Panfilo C., 1st Lieut.	SUGAR, Hyman S., Captain.
FEINERMAN, Albert H., 1st	THOMAS, Clyde O., Captain.
Lieut.	WILSON, Orley E., 1st Lieut.

11TH INFANTRY

BAUHOFF, Ned F., 1st Lieut.	GREENBERG, Morris Z., 1st
BUERMANN, Henry, Jr., 1st	Lieut.
Lieut.	KANNER, Irving F., 1st Lieut.
FELDMAN, Emanuel, 1st Lieut.	MARCUS, Louis L., 1st Lieut.
FLAX, Moses, 1st Lieut.	RIGHTMAN, Bert, 1st Lieut.
	STEIN, Albert F., 1st Lieut.

ARMY RESERVE OFFICERS ORDERED TO ACTIVE DUTY

SIXTH CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Sixth Corps Area, which comprises the states of Wisconsin, Michigan and Illinois:

BERNS, Robert S, Captain, Danville, Ill, Headquarters and Station Complement, Corps Area Service Command, Camp Davis, N C
DURHAM, Everett William, 1st Lieut, Dearborn, Mich, 202d Corps Area, Fort Bliss, Texas
FRIEDLAENDER, Sidney, 1st Lieut, Detroit, 33d Division, Camp Forrest, Tenn

ANDERSON, E Gilbert, 1st Lieut, Rockford, Ill
BRANDEL, John M, 1st Lieut, Owasco, Mich
CARY, Erwin C, Captain, Reedsville, Wis
CHRISTIANSON, Oscar O, Captain, Peoria, Ill, 1608th Corps Area Service Unit, Camp Grant, Ill
DUDEY, Edwin F, Major, Decatur, Ill
DVORAK, Harold J, Captain, Milwaukee
ESPEY, Hugh S, 1st Lieut, Chicago
FELDMAN, Harold, Captain, Pekin, Ill
GEHRINGER, Norman F, 1st Lieut, Pontiac, Mich
GOLDSTEIN, Hyman H, 1st Lieut, Chicago, 33d Division, Camp Forrest, Tenn

Orders Revoked

GIBSON, Thomas E, Captain, Lansing, Mich, Station Complement, Selfridge Field, Mich
HAUSMANN, Richard K, 1st Lieut, Waupun, Wis, 202d Corps Area, Fort Bliss, Texas
ROSEN, Benjamin B, 1st Lieut, Chicago, 33d Division, Camp Forrest, Tenn
VEDDER, Charles A, 1st Lieut, Marshfield, Wis, 1604th Corps Area Service Unit, Fort Brady, Mich
WADE, Chester, 1st Lieut, Chicago U. S Army Induction Station, Chicago

HIRSCH, Donald A, 1st Lieut, Chicago
JACOBS, Maurice B, 1st Lieut, Chicago
KEHL, Sylvester C, Major, Chicago
MANTELL, Bernard, 1st Lieut, Maywood, Ill
MARCUS, Daniel B, 1st Lieut, Detroit
NELSON, Charles A, 1st Lieut, Pekin, Ill
O'DONNELL, Steven P, 1st Lieut, Kiel, Wis
ROBERSON, Brooks L, 1st Lieut, Wood River, Ill
RUSKIN, Dave B, 1st Lieut, Wahjamega, Mich, 3d Armored Division, Camp Polk, La
SIMPSON, Reed Morgan, 1st Lieut, Medora, Ill
VERMEREN, Paul C, 1st Lieut, Chicago

SEVENTH CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Seventh Corps Area, which comprises the states of North Dakota, South Dakota, Minnesota, Nebraska, Iowa, Kansas, Missouri, Arkansas and Wyoming:

AHERN, Gerald Stehler, 1st Lieut, Minneapolis, 6th Medical Battalion, Fort Leonard Wood, Mo
AHRENS, John Heideman, 1st Lieut, University City, Mo, Corps Area Service Command, Replacement Center Infirmary, Fort Leonard Wood, Mo

ANDERSON, Wallace Everett, 1st Lieut, Thief River Falls, Minn, Camp Grant, Ill

ANNEBERG, Paul Daniel, 1st Lieut, Carroll, Iowa, Corps Area Service Command Engineers Replacement Center Infirmary, Fort Leonard Wood, Mo

ANSCHUTZ, Robert Ralph, 1st Lieut, Kansas City, Mo, Camp Grant, Ill

AYLWARD, Howard Joseph, 1st Lieut, Clayton, Mo, Corps Area Service Command Station Hospital, Camp J T Robinson, Ark

BACI, Donaciano E, 1st Lieut, Papillion, Neb, Corps Area Service Command Station Hospital, Fort Riley, Kan

BARKER, John Dennis, 1st Lieut, Warren, Minn, Air Base, Portland, Ore

BARKER Lawrence Fergusson, 1st Lieut, St Louis, 1st Field Artillery Battalion, Fort Leonard Wood, Mo

BARRENT, Milton Edward, 1st Lieut, Sioux City, Iowa, Camp Grant, Ill

BARRY, William Burnett, 1st Lieut, Kansas City, Mo, Corps Area Service Command, Station Hospital, Fort F E Warren, Wyo

BECHTOLD, Frederick Frank, 1st Lieut, St Louis, Corps Area Service Command Replacement Center Infirmary, Jefferson Barracks, Mo

BISHOP, Marion Dale, 1st Lieut, St Louis, Camp Grant, Ill

BLAIR, James Berl, 1st Lieut, Broken Bow, Neb, Corps Area Service Command, Engineer Replacement Center Infirmary, Fort Leonard Wood, Mo

BOYD, Eugene Judd, 1st Lieut, Iowa City, Corps Area Service Command Station Hospital, Fort Riley, Kan

BRADLEY, Ben Hughes, 1st Lieut, Richmond Heights, Mo, 20th Infantry, Fort Leonard Wood, Mo

BUELL, Arthur Louis, 1st Lieut, Batesville, Ark, Replacement Training Center, Camp Grant, Ill

BUSSABARGER, Robert Allison, 1st Lieut, Wardell, Mo, 43d Engineers, Camp J T Robinson, Ark

CAMPBELL, Harry Bryant, 1st Lieut, St. Louis, 20th Infantry, Fort Leonard Wood, Mo

CAMPBELL, Robert Evans Jr, 1st Lieut, Cedar Rapids, Iowa, Corps Area Service Command Induction Station, Fort Des Moines, Iowa

CARLSON, Elmer Henry, 1st Lieut, Muscatine, Iowa, Fort Leonard Wood, Mo

CARP, Oscar, 1st Lieut, Omaha, Corps Area Service Command Reception Center Infirmary, Camp J T Robinson, Ark

CASEY, Elmer Barney M, Lieut Colonel, St Louis, Camp Grant, Ill

CONTI, James Philip, 1st Lieut, St Louis, 20th Infantry, Fort Leonard Wood, Mo

COUCH, Orrie Alexander, Jr, 1st Lieut, Iowa City, Iowa, Camp Grant, Ill

CURTIS, William Shepley, 1st Lieut, St Louis, Camp Grant, Ill

DAVIS, Christopher Gates, 1st Lieut, Kansas City, Kan, Camp Grant, Ill

DEW, Hogan Allen, 1st Lieut, Hamburg, Ark, 1st Infantry, Fort Leonard Wood, Mo

DONNELLY, Bernard Aloysius, 1st Lieut, Iowa City, Fort Douglas, Utah

DORMAN, John Wesley, 1st Lieut, Dyess, Ark, 142d Field Artillery, Fort Sill, Okla

DRAKE, Charles Centennial, Jr, 1st Lieut, St Louis, McChord Field, Tacoma, Wash

DREXLER, George Warren, 1st Lieut, Minneapolis, 1st Infantry, Fort Leonard Wood, Mo

DUPONT, Joseph Arthur, 1st Lieut, Excelsior, Minn, 6th Medical Battalion, Fort Leonard Wood, Mo

ELLIOTT, William Henry, Jr, 1st Lieut, St Louis, Corps Area Service Command Station Hospital, Fort Meade, S D

EVANS, Byron Henry, 1st Lieut, Cedar Rapids, Iowa, Camp Grant, Ill

FERGUSON, Lewis Hamilton, 1st Lieut, St Louis, Camp Grant, Ill

FLYNN, John Timothy, 1st Lieut, St Louis, Fort Leonard Wood, Mo

FOSTER, Miles Everett, 1st Lieut, St Louis, Fort Leonard Wood, Mo

GALT, Charles E. Jr, 1st Lieut, Ferguson, Mo, Camp Grant, Ill

GARETZ, Michael Allen, 1st Lieut, Minneapolis, 6th Medical Battalion, Fort Leonard Wood, Mo

GARRETT, Glenn Harley, 1st Lieut, Clay Center, Kan, for temporary duty with Medical Replacement Training Center, Camp Grant, Ill

GATES, Charles Lee, 1st Lieut, Ulrich, Mo, Corps Area Service Command Station Hospital, Fort Leavenworth, Kan

GEPPERT, Leo Joseph, 1st Lieut, Vermillion, S D, Camp Grant, Ill

GERSON, Charles Everett, 1st Lieut, St Louis, Corps Area Service Command Station Hospital, Fort Leonard Wood, Mo

GLASSMAN, Arthur Leonard, 1st Lieut, Iowa City, Engineers Replacement Center Infirmary, Fort Leonard Wood, Mo

GRAVES, James Huntington, 1st Lieut, St Paul, 92d Engineer Battalion, Fort Leonard Wood, Mo

GRAY, Herschel Fredrick, 1st Lieut, Little Rock, Ark, 1st Infantry, Fort Leonard Wood, Mo

GREENHOUSE, Jerome Mayer, 1st Lieut, University City, Mo, Camp Grant, Ill

GREGORY, Kendall Deertur, 1st Lieut, St Louis, Camp Grant, Ill

HAMILTON, Charles Terrill, 1st Lieut, Iowa City, Corps Area Service Command Station Hospital, Fort Leonard Wood, Mo

HAMILTON, Ralph Block, 1st Lieut, West Memphis, Ark, Air Base (Nonflying status), Everett, Wash

HARPER, Harry Penn, 1st Lieut, Rochester, Minn, Corps Area Service Command Station Hospital, Fort Riley, Kan

HARRIS, Charles Preston, 1st Lieut, Leachville, Ark, Air Base (Nonflying status), Pendleton, Ore

HAWES, William John, Major, Columbia, Mo, Headquarters and Headquarters Battery, 6th Division Artillery, Fort Leonard Wood, Mo

HAZLET, Kenneth Kirk, Iowa City, Corps Area Service Command Station Hospital, Fort Leonard Wood, Mo

HEIMANN, Verne Rodney C, 1st Lieut, Albia, Iowa, Corps Area Service Command Induction Station, Fort Snelling, Minn

HEITZMAN, Paul Otto, 1st Lieut, Burlington, Iowa, 51st Field Artillery Battalion, Fort Leonard Wood, Mo

HENDERSON, Walker Bland, Major, Oelwein, Iowa, 6th Medical Battalion, Fort Leonard Wood, Mo

HEYWOOD, Leo Thomas, 1st Lieut, Omaha, Fort Leonard Wood, Mo

HILGER, David William, 1st Lieut, St. Paul, Corps Area Service Command Induction Station, Fort Leavenworth, Kan

HOBERT, Francis William, Captain, Lake City, Iowa, Medical Replacement Center, Camp Grant, Ill

HOGABOOM, Gilbert Murray, 1st Lieut, Hot Springs, Ark, 35th Division, Camp Joseph T Robinson, Ark
 HOFFMAN, George Robert, 1st Lieut, Minneapolis, 1st Infantry, Fort Leonard Wood, Mo
 HOLLENHORST, Robert William, 1st Lieut, St Cloud, Minn, 6th Medical Battalion, Fort Leonard Wood, Mo
 HOPKINS, Florian Goss, 1st Lieut, Gideon, Mo, Corps Area Service Command Station Hospital, Camp J T Robinson, Ark
 HOTTINGER, Raymond Creighton, 1st Lieut, Jamesville, Minn, Fort George Wright, Spokane, Wash
 HOWE, Louis Francis, Captain, Union, Mo, Medical Replacement Center, Camp Grant, Ill
 HUBER, Tiron Ehrhart, 1st Lieut, St Louis, Camp Grant, Ill
 HURST, Thomas Charles, 1st Lieut, Kansas City, Mo, Camp Grant, Ill
 JANUARY, Lewis Edward, 1st Lieut, Iowa City, Corps Area Service Command Quartermaster Replacement Center Infirmary, Fort F E Warren, Wyo
 JOHNSON, Robert Hall, 1st Lieut, St Louis, 6th Medical Battalion, Fort Leonard Wood, Mo
 JORDAN, Raymond Ellsworth, 1st Lieut, St Louis, Medical Replacement Training Center, Camp Grant, Ill
 KAISER, Max Elliott, 1st Lieut, Ottawa, Kan, Medical Replacement Center, Camp Grant, Ill
 KEOHEN, Gerald Francis, 1st Lieut, Iowa City, Iowa, Camp Grant, Ill
 KILTZ, Richard Clyde, Captain, Omaha, Corps Area Service Command Induction Station, Fort Cook, Neb
 KIMBALL, John Egbert, Jr, 1st Lieut, St Louis, Camp Grant, Ill
 KINGSLAND, Robert Chenault, 1st Lieut, St Louis, Corps Area Service Command Station Hospital, Fort Crook, Neb
 KLAIT, Daniel David, 1st Lieut, St Louis, for temporary duty with Medical Replacement Training Center, Camp Grant, Ill
 KNIGHT, William Allen, Jr, 1st Lieut, St Louis, Camp Grant, Ill
 KOBER, William Melvin, 1st Lieut, Little Rock, Ark, 4th Cavalry, Fort Meade, S D
 KOTNER, Lawrence Melvin, 1st Lieut, University City, Mo, Quartermaster Replacement Center Infirmary, Fort F E Warren, Wyo
 KRAVITZ, Morton Atherton, 1st Lieut, Kansas City, Corps Area Service Command Station Hospital, Fort Riley, Kan
 KUGLER, Frank Elbert, 1st Lieut, Iowa City, Corps Area Service Command Station Hospital, Fort F E Warren, Wyo
 KURIS, David B, 1st Lieut, Duluth, Minn, 6th Medical Battalion, Fort Leonard Wood, Mo
 LAKAYTIS, Charles Alexandra, 1st Lieut, Kansas City, Mo, Camp Grant, Ill
 LATTUADA, Henry Deter, 1st Lieut, St Louis, Replacement Training Center, Camp Grant, Ill
 LAUDICINA, August, 1st Lieut, St Louis, Corps Area Service Command Station Hospital, Fort Snelling, Minn
 LEE, Wayne Robert, 1st Lieut, Burlington, Iowa, Corps Area Service Command Quartermaster Replacement Center Infirmary, Fort F E Warren, Wyo
 LIMAURO, Andrew Benedict, 1st Lieut, St Louis, Camp Grant, Ill
 LINDLEY, Ellsworth LaVerne, 1st Lieut, Muscatine, Iowa, 1st Infantry, Fort Leonard Wood, Mo
 LONDON, Lewis Bolter, 1st Lieut, Little Rock, Ark, Corps Area Service Command Station Hospital, Camp J T Robinson, Ark
 LONERGAN, Warren Mellies, 1st Lieut, St Louis, Camp Grant, Ill
 LOVE, William Robert, 1st Lieut, Rochester, Minn, Corps Area Service Command Station Hospital, Fort Snelling, Minn
 MACDONALD, William Charles, 1st Lieut, St Louis, Camp Grant, Ill
 MCCAIN, Donovan Legare, 1st Lieut, St Paul, Corps Area Service Command Station Hospital, Fort F E Warren, Wyo
 MCCONKIE, Edwin Bruce, Captain, Cedar Rapids, Iowa, Corps Area Service Command Replacement Center Infirmary, Jefferson Barracks, Mo

McDONALD, George James, 1st Lieut, St Louis, Corps Area Service Command Station Hospital, Fort Snelling, Minn
 MCGOARTY, Brian John, 1st Lieut, Easton, Minn, Camp Grant, Ill
 McKEE, Leo Francis, 1st Lieut, Kansas City, Kan, Corps Area Service Command, Replacement Center Infirmary, Fort Leonard Wood, Mo
 MACKENBROCH, Frederick Caspar, 1st Lieut, Omaha, Corps Area Service Command Station Hospital, Fort Leonard Wood, Mo
 MADDUX, William Paul, 1st Lieut, Buffalo, Mo, Quartermaster Replacement Center Infirmary, Fort F E Warren, Wyo
 MARK, Hilbert, Major, Minneapolis, Camp Grant, Ill
 MARKING, George Henry, 1st Lieut, Osseo, Minn, Camp Grant, Ill
 MELLIES, Chester John, Captain, Mount Vernon, Mo, Corps Area Service Command Station Hospital, Fort Riley, Kan
 MERENDA, Sam John, 1st Lieut, St Louis, 6th Division Headquarters and Headquarters Battery, Fort Leonard Wood, Mo
 MERRILL, Robert Lowe, 1st Lieut, St Louis Camp Grant, Ill
 MINGE, Raymond Kenneth, 1st Lieut, Clarkfield, Minn, 92d Engineer Battalion, Fort Leonard Wood, Mo
 MIRA, Joseph John, 1st Lieut, St Louis, Camp Grant, Ill
 MOEN, Berwyn Harold, 1st Lieut, Inwood, Iowa, Camp Grant, Ill
 MORGAN, John Lloyd, 1st Lieut, Emporia, Kan, Camp Grant, Ill
 MULLER, Albrecht Eugene, 1st Lieut, St Paul, 6th Medical Battalion, Fort Leonard Wood, Mo
 MUNDT, Leslie Krow, 1st Lieut, Helena, Ark, Corps Area Service Command Station Hospital, Fort Leonard Wood, Mo
 MUNSCH, Girard Augustus, 1st Lieut, St Louis, Camp Grant, Ill
 MURRAY, Edward Stevenson, 1st Lieut, Cedar Rapids, Iowa, Corps Area Service Command Quartermaster Replacement Center Infirmary, Fort F E Warren, Wyo
 NESTER, Charles Adolph, 1st Lieut, St Louis Camp Grant, Ill
 NEURNBERGER, Robert Earl, 1st Lieut, Omaha, 80th Field Artillery Battalion, Fort Leonard Wood, Mo
 NOTHNAGEL, Arnold Fred, 1st Lieut, Kansas City, Kan, Corps Area Service Command Station Hospital, Fort Riley, Kan
 OGBORN, Robert James, 1st Lieut, Sioux Falls, S D, 6th Medical Battalion, Fort Leonard Wood, Mo
 OLSON, Alton Curtis, 1st Lieut, Minneapolis, Corps Area Service Command Station Hospital, Fort Riley, Kan
 OLSON, Duane Charles, 1st Lieut, Gaylord, Minn, Camp Grant, Ill
 QUATTLEBAUM, Frank Walter, 1st Lieut, Crookston, Minn, Camp Grant, Ill
 PANGBURN, Merrill Walter, 1st Lieut, Miller, S D, nonflying status, Moffett Field, Calif
 PASSANANTE, Bartholomew M, 1st Lieut, University City, Mo, 63d Infantry, Fort Leonard Wood, Mo
 PAYNE, Voris Ralph, 1st Lieut, St Louis, Camp Grant, Ill
 PETTERSON, Cecil Edward, 1st Lieut, Norton, Kan, Ogden Air Depot (nonflying status), Ogden, Utah
 POHLMAN, John Francis, 1st Lieut, Wichita, Kan, Camp Grant, Ill
 RICH, George Theodore, 1st Lieut, Grand Forks, N D, Corps Area Service Command Station Hospital, Fort Leonard Wood, Mo
 RLEVES, Eugene Albert, 1st Lieut, Kansas City, Kan, Camp Grant, Ill
 REID, Joe Winston, 1st Lieut, Arkadelphia, Ark, Camp Grant, Ill
 RITTER, Eugene Francis, 1st Lieut, Coatesville, Mo, 6th Engineer Battalion, Fort Leonard Wood, Mo
 ROBERTSON, Howard Thomas, 1st Lieut, Concordia, Kan, Camp Grant, Ill
 RODMAN, George Hurst, 1st Lieut, St Louis, Camp Grant, Ill
 SAAR, John William, 1st Lieut, Salt Lake City, Ogden Air Depot (nonflying status), Ogden, Utah
 SCALES, James Russell, 1st Lieut, Rochester, Minn, 6th Engineer Battalion, Fort Leonard Wood, Mo

Orders Revoked

AAGESEN, Carl A, 1st Lieut, Dows, Iowa
 AYLWARD, Howard Joseph, 1st Lieut, Clayton, Mo, 6th Division, Headquarters and Headquarters Battery, Fort Leonard Wood, Mo
 BAILEY, William H, 1st Lieut, St. Louis
 BEBER, Meyer, Captain, Omaha
 BERMAN, William, 1st Lieut, St Louis
 BIRGE, Richard Fuller, Captain, Des Moines, Iowa, Corps Area Service Command Station Hospital, Fort Leonard Wood, Mo
 BLAIR, James Berl, 1st Lieut, Broken Bow, Neb
 BOE, Henry, Captain, Sioux City, Iowa
 BOLEY, James O, 1st Lieut, Pilot Grove, Mo
 BURT, Elmer G, 1st Lieut, Crossett, Ark
 BUZZELLE, Leonard K, 1st Lieut, Minneapolis
 CAIRNS, Robert J, 1st Lieut, Sanborn, Minn
 DECKER, Rudolph F, Captain, Byron, Neb
 DRACE, Charles Centennial, Jr, 1st Lieut, St Louis
 DREWLER, George Warren, 1st Lieut, Minneapolis
 EDWARDS, Thomas Jefferson, 1st Lieut, St Paul, Corps Area Service Command Station Hospital, Fort Leonard Wood, Mo
 ENGLISH, Wallace D, Captain, Cardwell, Mo
 ERICKSON, Clarence Wilber, 1st Lieut, Pittsburg, Kansas, Corps Area Service Command Station Hospital, Fort Crook, Neb
 FAST, William S, 1st Lieut, Atchison, Kan
 FLICKINGER, Roger R, 1st Lieut, Mason City, Iowa
 FLINN, John Timothy, 1st Lieut, St Louis, Corps Area Service Station Hospital, Fort Leonard Wood, Mo
 GRAY, Herschel Fredrick, 1st Lieut, Little Rock, Ark, 1st Infantry, Fort Leonard Wood, Mo
 HAGAN, Francis J, 1st Lieut, Wichita, Kan
 HAMILTON, Benjamin C, Jr, Major, Jefferson, Iowa
 HAWMOND, Harold E, Captain, Perry, Iowa

HENDERSON, Robert W, Captain, Bismarck, N D
 HOBART, Francis William, Captain, Lake City, Iowa
 HOBBS, Russell E, 1st Lieut, Wichita, Kan
 HOFFMAN, Jacob S, 1st Lieut, Kansas City, Mo
 HOWE, Louis Francis, Captain, Union, Mo, Medical Department Replacement Center, Camp Grant, Ill
 HUBER, Melvin J, Captain, St Louis
 HUGHES, Shelby B, 1st Lieut, Clinton, Mo
 HYNDMAN, Henry H, 1st Lieut, Wichita, Kan
 JEWELL, Iverson H, Lieut, Colonel, Paris, Ark
 JOHNSTON, Thomas S, Captain, Topock, Kan
 LEIFER, William W, 1st Lieut, Kansas City, Mo
 McVAY, Melvin J, Captain, Lake City, Iowa
 MADDUX, William Paul, 1st Lieut, Buffalo, Mo
 MINER, Paul Floyd, 1st Lieut, Laramie, Wyo, 35th Division, Camp J T Robinson, Ark
 MINGE, Raymond Kenneth, 1st Lieut, Clarkfield, Minn
 PLATOU, Ralph V, 1st Lieut, Minneapolis
 POTASHNICK, Robert, 1st Lieut, St Louis, Camp Roberts, Calif
 REED, Charles C, 1st Lieut, Little Rock, Ark
 SETTLE, Emmett B, Captain, Rockport, Me
 SHANDORF, James F, 1st Lieut, Northfield, Minn
 SHELTON, Harold J, Captain, Webster Groves, Mo
 SHEPARD, Walter Lee, 1st Lieut, Pittsburg, Kan
 SICELUFF, Joseph G, 1st Lieut, Springfield, Mo
 SPAFFORD, Allen L, Captain, Oawatomie, Kan
 STEELE, Hugh H, 1st Lieut, Deadwood, S D
 TROW, James Edward, 1st Lieut, Minneapolis
 VAN BESIEEN, George J, 1st Lieut, Decorah, Iowa
 WETRICH, Max Franklin, 1st Lieut, Des Moines, Iowa, 63d Infantry, Fort Leonard Wood, Mo

ORGANIZATION SECTION

WOMAN'S AUXILIARY

Death of Mrs. Red

Mrs. Samuel Clark Red of Houston, Texas, founder of the Woman's Auxiliary to the American Medical Association, died suddenly on August 10. Mrs. Red was the first president of the Auxiliary to the American Medical Association (1922-1923) and was also president for the two succeeding years.

Arkansas

On March 13 Mrs. James Lewis, retiring president of the auxiliary to the Washington County Medical Society, was hostess to members at a dinner bridge; officers for next year were elected as follows: president, Mrs. E. F. Ellis, Fayetteville; vice president, Mrs. R. T. Henry, Springdale; secretary, Mrs. P. L. Hathcock Jr.; treasurer, Mrs. R. H. Huntington. On March 20 the annual City Hospital Shower and Tea was given by the auxiliary. About 100 guests were present and six hundred gifts for the hospital were received. Mrs. Fount Richardson was general chairman of the tea. On March 24 Mrs. James Lewis read a paper before the Business and Professional Woman's Club of Fayetteville at the showing of the picture "Choose to Live," sponsored by the Woman's Auxiliary to the American Medical Association. On March 25 the auxiliary sponsored the same picture with the P. T. A. at the high school auditorium, to which the public is invited.

California

On April 15 the Sacramento auxiliary sponsored a fashion show for juveniles, the models being twenty daughters and sons of the group.

One hundred thirty-three members and guests of the Los Angeles County auxiliary met at the Annandale Golf Club in Pasadena to hear Mrs. Thomas G. Winter of the Motion Picture Producers and Distributors of America talk on "The Pictures and the Political Crisis."

Colorado

The auxiliary to the Denver County Medical Society met April 21 at the Colorado General Hospital nurses' home to hear a dramatization by Jeanette Humphreys of the play entitled "George Washington Slept Here." The members brought their banks for the benefit of cancer control.

Indiana

Dr. Doster Buckner addressed the Allen County medical auxiliary March 18 in Fort Wayne on "Danger in Laity Discussion of Scientific Information." Dr. Jessie Calvin, vice commander in the Woman's Field Army for Cancer Control, talked on "Cancer Control," and Mrs. A. N. Ferguson discussed "The Case of the United States vs. The American Medical Association et al." The auxiliary has arranged to distribute toys in the pediatric wards of Fort Wayne hospitals.

Seventeen members attended the dinner meeting of the auxiliary to the Delaware-Blackford Counties Medical Society in Muncie on March 18. The group recently gave the physicians \$40 to purchase a dictionary for the physicians' library in the Ball Memorial Hospital.

The members from Nappanee planned the program for the meeting on March 6 of the Elkhart County auxiliary. Mrs. Howard A. Bosler, whose husband has been a physician in Nigeria, West Africa, described her experiences as a doctor's wife there. On March 20 the Elkhart County Medical Society was addressed by Dr. Bosler, who gave an account of his work in Nigeria.

The LaPorte County auxiliary held a dinner meeting in Michigan City on March 20. Following the dinner, the discussion of socialized medicine was led by a member of the Michigan City League of Women Voters.

The Madison County auxiliary is proud of the success of its program in which it sponsored a drawing for a prize of \$300

or a trip to Mexico or California, the winner to make his own choice. The funds raised in this way were used for guild purchases of various supplies and equipment for St. John's Hospital.

The Tippecanoe County auxiliary has been experimenting; at each meeting it has a "news flash" of up to the minute news pertaining directly or indirectly to the medical world. This tends to encourage the members to watch for news items to report and is a step toward an informed public. The auxiliary is confining its programs to ones of an educational nature and letting the social part be secondary.

Iowa

The Woman's Auxiliary to the Upper Des Moines Medical Society met at Spirit Lake, July 10. Mrs. W. R. Hornaday of Des Moines, president of the auxiliary to the Iowa State Medical Society, stressed the aims and purposes of the auxiliary, which she cited as being (1) social, (2) a means of contact between the medical profession and laymen and (3) the necessity of having at least one health program annually in each auxiliary. The following officers were elected for the coming year: Mrs. Don F. Rodawig of Spirit Lake, president; Mrs. Paul O. Nelson of Emmetsburg, vice president; Mrs. Andrew I. Reed of Estherville, secretary and treasurer, and Mrs. Elbert E. Munger Jr. of Spencer, ex-committee member from Clay County.

The Woman's Auxiliary to the Dubuque County Medical Society held its annual meeting April 8. Mrs. E. T. Warren, president of the state auxiliary, was guest of honor. Miss Janice Bardill played piano selections.

Wives of physicians met with Mrs. E. T. Warren of Stuart, president of the state auxiliary, April 3 in Jefferson and organized the Woman's Auxiliary to the Greene County Medical Society. The following officers were elected: Mrs. Phillips E. Lohr of Churdan, president; Mrs. Roy E. Parry of Seranton, president-elect; Mrs. Walter E. Chase of Rippey, secretary and treasurer, and Mrs. Laurence C. Hanson of Jefferson, chairman of the Hygeia committee.

North Carolina

The nineteenth session of the Woman's Auxiliary to the Medical Society of the State of North Carolina was held at Pinhurst, Tuesday, May 20. Mrs. Clyde R. Hedrick of Lenoir, president, presided. Dr. Hubert B. Haywood, president of the Medical Society of the State of North Carolina, was guest speaker. The chairman of the committee on research, Mrs. R. S. McGeachy of New Bern, gave a paper on the life of the late Dr. Martin L. Stevens, for whom the bed which the woman's auxiliary will support at Black Mountain Sanatorium is named. The report of the nomination committee was as follows: Mrs. Sidney Smith, Raleigh, president; Mrs. R. A. Moore, Winston-Salem, president-elect; Mrs. C. R. Hedrick, Lenoir, first vice president; Mrs. J. R. Terry, Lexington, second vice president; Mrs. J. S. Hooker, Chapel Hill, third vice president; Mrs. Harry Winkler, Charlotte, corresponding secretary and recording secretary, and Mrs. E. C. Judd, Raleigh, treasurer.

Pennsylvania

The auxiliary of the Westmoreland County Medical Society was addressed May 6 by Dr. W. W. Bauer of Chicago, director of the Bureau of Health Education of the American Medical Association on "The Skin You Love to Retouch." Dr. Bauer had addressed high school students in the morning and the Rotary Club at noon. The auxiliary has given thirty-eight subscriptions of *Hygeia* to schools and libraries in the county during the past year. Miss Ann Carlisle played during the tea; high school girls were aides, Mrs. R. E. L. McCormick of Irwin was chairman of the tea arrangements and Mrs. J. Morgan Meyhew of Greensburg had charge of the program.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

ALABAMA

Changes in Health Personnel.—Dr William A. Dodson Jr., Double Springs, has resigned as health officer of Winston County to take a position with the U. S. Public Health Service, it is reported.—Dr William J. Donald, Brewton, has been appointed an associate in county organization in the state department of health, Montgomery, to succeed Dr W. D. Burkhalter, who recently became health officer of Shelby County of Memphis, Tenn.—Dewitt Sterling Abell, M.S., a member of the staff of the North Carolina State Department of Health, has been appointed director of the bureau of sanitation in the Alabama State Health Department.

ARKANSAS

Medical Alumni Officers.—Dr Eugene A. Callahan, Carlisle, was elected president of the Alumni Association of the University of Arkansas School of Medicine, Dr Estes Allen, Little Rock, vice president, Dr Thomas Duell Brown, secretary, and Dr Paul M. Fulmer, Little Rock, treasurer.

District Meeting.—The Ninth Councilor District Medical Society met at the Hotel Seville, Harrison, recently, with the following speakers:

Dr Arthur M. Washburn, Little Rock, Tularemia
Dr Le Roy F. Heimburger, Springfield, Mo., Fungi in Eczematous Dermatitis of the Hands
Dr Walter S. Sewell, Springfield Mo., Diseases of the Prostate
Dr Charles S. Paddock, Fayetteville, Urologic Problems That Daily Confront the Physician
Dr Louis K. Hundley, Harrison, Trichoma in Arkansas

Society News.—The Mississippi County Medical Society was addressed recently by Drs Robert Lyle Motley and Thomas D. Moore, Memphis, on "Indigestion" and "Ureteral Kinks and Strictures" respectively.—Dr James T. Powell, Gravette, discussed podalic version and solution of posterior pterygia before the Benton County Medical Society, June 12, at Gravette.—A joint dinner session of the Sebastian County Medical Society and the Muskogee County (Okla.) Medical Society, June 10, in Fort Smith was addressed by Drs Henry T. Ballantine, Muskogee, on "Anomalies of the Newborn" and Frederic G. Dorwart, Muskogee, "Massive Collapse of the Lung and Pneumothorax."—Drs Francis Walter Carruthers and Paul L. Mahoney, Little Rock, addressed the Southeast Arkansas Medical Society in Crossett, June 16, on "Synovectomy in Knee Joint Conditions" and "Chronic Cough" respectively. Dr Herbert Fay H. Jones, Little Rock, president of the Arkansas Medical Society, also made an address.—Dr Willard W. M. Allen, St. Louis, addressed the Pulaski County Medical Society, June 23, on "Clinical Use of Sex Hormones."

FLORIDA

Annual Postgraduate Course.—The Florida Medical Association and the Florida State Board of Health sponsored their ninth annual short course for physicians in Jacksonville in June. Speakers who gave several lectures each were:

Medicine: Dr Henry M. Thomas Jr., Baltimore
Surgery: Dr Richard B. Cattell, Boston
Obstetrics: Dr Nicholson J. Eastman, Baltimore
Pediatrics: Dr Daniel C. Darrow, New Haven, Conn.
Gynecology: Dr Everett D. Pliss, Iowa City
Venereal diseases: Dr Charles F. Mohr, Baltimore
Military Medicine: Col. Luther R. Poust, Lieut. Col. Bennett G. Owens, Major James A. Coleman, all of Camp Blending, and Comdr. Eben E. Smith, Naval Air Station, Jacksonville.

GEORGIA

Memorial to Dr. E. C. Davis.—Plans to establish a memorial for the late Dr. Edward Campbell Davis in the new Academy Building, home of the Fulton County Medical Society Atlanta, have been announced. Dr. Davis died in 1931. A graduate of the University of Louisville School of Medicine in 1892, Dr. Davis was emeritus professor of obstetrics and gynecology at Emory University School of Medicine, a founder of the Davis-Fischer Sanatorium and, in 1928, president of the Fulton County Medical Society.

ILLINOIS

Family Health Consultations at State Fair.—Family health consultations were a feature of the state fair exhibits of the Illinois State Department of Public Health at the Exposition Building in Springfield, August 9-17. This feature supplanted the discontinued baby conference and consisted of consultation booths open to adults, infants and children of all ages. Trained specialists in public health engineering, nursing, sanitation, preventive medicine, mental hygiene and nutrition were on hand to discuss general health problems with visitors at the fair.

Chicago

Personal.—Dr Samuel M. Feinberg has been elected an honorary member of the Argentine Society for the Study of Allergy.—Mr. Charles A. Wordell, director of St. Luke's Hospital for thirteen years, has resigned to become superintendent of the Hospital for Children, San Francisco, effective September 1.

Dr. McNally Appointed Toxicologist.—Dr William D. McNally, who is said to have been responsible for the establishment of the first laboratory for toxicology in the nation for the Cook County coroner's office in 1913, has again been appointed toxicologist for the county, effective August 11. He succeeds Clarence W. Muehlberger, Ph.D., who has become toxicologist for the state of Michigan. Dr. McNally served as toxicologist and chief chemist of Cook County from 1913 to 1929. He was instructor in chemistry at the University of Illinois from 1905 to 1906, when he went to Armour & Company as chemist. He was chief chemist of the Chicago Department of Health from 1910 to 1913. Since 1923 he has been associate professor of materia medica and toxicology at Rush Medical College. He graduated at Rush in 1920. Dr. Muehlberger had been county toxicologist since 1930. He came from Wisconsin, where he had been state toxicologist since 1923 and assistant professor of pharmacology and toxicology at the University of Wisconsin Medical School, Madison, since 1924. Dr. Muehlberger was toxicologist and assistant director of the Scientific Crime Detection Laboratory at Northwestern University Medical School, 1930-1935 and had held teaching positions at Northwestern, Illinois and the University of Chicago, Department of Medicine.

MASSACHUSETTS

Dr. Beecher Lectures in Bogotá.—The U. S. Department of State awarded a travel grant to Dr. Henry K. Beecher, associate in anesthesia, Harvard Medical School, Boston, to give a series of lectures during June and July at the National University of Colombia at Bogotá, Science reports.

Promotions on Harvard Faculty.—The following promotions on the faculty of Harvard Medical School, Boston, were recently announced, among others:

Donald L. Augustine, M.D., associate professor of comparative pathology and tropical medicine
Dr. William L. Aycock, associate professor of preventive medicine and hygiene
Dr. Harry C. Solomon, clinical professor of psychiatry
Dr. Charles G. Mixer, clinical professor of surgery
Dr. Robert S. Morison, assistant professor of anatomy
Dr. Thomas D. Jones, assistant professor of medicine
Dr. Aubrey O. Hampton, assistant professor of roentgenology
Dr. Arthur T. Hertig, assistant professor of pathology
Dr. Jacob Fine, assistant professor of surgery
Dr. Harold G. Tobey, lecturer on laryngology
Dr. Charles T. Porter, lecturer on otology
Dr. George G. Smith, lecturer in genitourinary surgery

MICHIGAN

New Health Units.—A new city-county health unit has been established in Kalamazoo County under the direction of Dr. Irmel W. Brown, formerly health officer of Kalamazoo, who has returned from a year's study in public health. This is the first city-county unit in Michigan. There are now sixty-five counties in the state with full time public health services and eighteen counties without such protection.

Dr. Francis Named Professor of Epidemiology.—Dr. Thomas Francis Jr., professor of bacteriology and director of the bacteriologic laboratories, New York University College of Medicine, New York, has been appointed professor and head of the department of epidemiology at the new School of Public Health at the University of Michigan, Ann Arbor. Dr. Francis was born in Indiana in 1899. He graduated at Yale University School of Medicine, New Haven in 1925. He was at one time resident physician at the Hospital of the Rockefeller Institute and associate in medicine at the Rockefeller Institute. He has been a member of the staff of the International Health Division of the Rockefeller Foundation since 1936.

OREGON

State Medical Meeting in Portland.—The sixty-seventh annual session and postgraduate assembly of the Oregon State Medical Society will be held in Portland, September 3-6, under the presidency of Dr. Karl H. Martzloff, Portland. Dr. Frank H. Lahey, Boston, President of the American Medical Association, will deliver an address on "Some of the Newer Developments in Medicine and Surgery," and three other guests will give three lectures each as follows:

Dr. George M. Curtis, Columbus, Ohio: Iodine and Calcium Metabolism in Thyroid Disease; Recent Advances in Thoracic Surgery; Recognition and Management of Acute Injury to the Chest.

Dr. Henry J. Tumen, Philadelphia: Diagnosis and Treatment of Jaundice; Management of Patient with Irritable Colon; Clinical and Gastroscopic Features of Chronic Gastritis.

Dr. Milton B. Cohen, Cleveland: Nature of Allergy, Its Pathology and Mechanisms of Its Production; Management of Patients with Asthma, Hay Fever and Other Allergic States; Growth Disturbances Produced by Allergy.

Panel discussions dealing with subjects in medicine, surgery, orthopedics, obstetrics and gynecology, dermatology and syphilology, allergy, psychiatry and radiology are also announced.

RHODE ISLAND

Personal.—Dr. William P. Shields, Providence, has been appointed epidemiologist in the state health department to succeed Dr. Harry B. Neagle, who resigned because of ill health.

—Dr. John E. Donley, Providence, has been named to an eleven member state council of defense by Governor McGrath.

—Dr. Henry A. Jones, Cranston, formerly superintendent of the State Infirmary, Howard, has been appointed assistant to the state director of social welfare.

SOUTH CAROLINA

Personal.—Dr. James C. Brabham, Walterboro, health officer of Colleton County, has been appointed health officer of Laurens and Union counties, succeeding Dr. Henry R. Perkins, Laurens. Dr. Lloyd W. Luttrell, Pickens, has been transferred from the health unit in Pickens County to succeed Dr. Brabham in Colleton County.

Society News.—Dr. James L. Hughes, Greer, among others, addressed the Greenville County Medical Society, Greenville, July 7, on "Borderline Deficiency Diseases."—Dr. William Halsey Barker, Baltimore, addressed the June meeting of the Florence County Medical Society, Florence, on "Uses and Abuses of the Sulfonamide Drugs." Dr. William R. Barron, Columbia, addressed the society, July 8, on "Prostatic Surgery."

VIRGINIA

Faculty Changes at University of Virginia.—Dr. Claude C. Coleman, clinical professor of neurological surgery at the University of Virginia Medical Department, Charlottesville, since 1937, has resigned. His successor will be Dr. William Gayle Crutchfield, Richmond, who has been associate clinical professor since 1937. Dr. John M. Meredith, assistant professor in the department, has also resigned and will now become associate professor of neurological surgery in the Medical College of Virginia, Richmond.

PUERTO RICO

Plan to Treat Rejected Selectees with Venereal Disease.—The director of the bureau of venereal diseases in the Puerto Rico Department of Health, Dr. Ernesto Quintero, San Juan, has recently given instructions to physicians in charge of the department's clinics for collaboration with selective service boards in bringing under treatment all men rejected by the boards because of venereal disease. The director recommends that a procedure be arranged by which health officials will be informed by the boards of all such cases. Treatment is to be offered free to the infected persons; their contacts are to be investigated and treatment also offered to any of those who are found to have venereal diseases. A follow-up system to keep patients under treatment was recommended, with a plan for reporting to the selective service boards any who stop treatment. Dr. Quintero recommended a similar program for workers in defense industries. Finally he urged an intensive educational program among selective service registrants, members of the armed forces and defense workers to keep them out of the hands of charlatans.

GENERAL

Changes in Status of Licensure.—The Board of Medical Examiners of Maryland recently reported the following action:

Dr. Henry L. Fabrney, Frederick, license restored February 11.

The Massachusetts Board of Registration in Medicine announces the following action:

Dr. Manford R. Spalding, Auburn, license suspended, July 11, for deceit in the writing of a narcotic prescription.

The Minnesota State Board of Medical Examiners, St. Paul, announces the following action:

Dr. Samuel R. Fraker, Minneapolis, license revoked, May 9, having pleaded guilty to a charge of performing an illegal operation.

Report on Encephalitis Outbreak.—Newspapers reported on August 13 that at least eighty-four deaths have been attributed to an outbreak of encephalitis in five midwestern states in the last two months. More than 800 persons were ill with the disease. Forty-six deaths and 400 cases were reported in North Dakota since the beginning of the outbreak; Minnesota, twenty-four deaths and 366 cases; South Dakota, ten deaths and 70 cases, and, since July 28, Nebraska, four deaths and Iowa, 10 cases. Four new cases were reported in Winnipeg, Canada, bringing the total of cases in Manitoba this year to 21, with three deaths.

Examinations in Obstetrics and Gynecology.—The American Board of Obstetrics and Gynecology announces that its next examination and review of case histories (part I) for group B candidates will be held in various cities of the United States and Canada on Jan. 3, 1942. Applications for admission to these examinations must be on file in the office of the secretary, Dr. Paul Titus, Pittsburgh, not later than October 1. The general oral and pathologic examinations (part II) for all candidates (groups A and B) will be conducted by the entire board in Atlantic City immediately prior to the 1942 meeting of the American Medical Association. The present fiscal year (1941-1942) marks the close of the two groups of classification of applicants for examination. Thereafter the board will have only one classification of candidates. Information and application blanks may be obtained from Dr. Titus, 1015 Highland Building, Pittsburgh.

Meeting of Railway Surgeons.—The fifty-second annual meeting of the American Association of Railway Surgeons will be held at the Palmer House, Chicago, September 8-10, under the presidency of Dr. Lucien Stark, Norfolk, Neb. The speakers will include:

Dr. Stanley J. Seeger, Milwaukee, Treatment of Burns.

Dr. M. Herbert Barker, Chicago, Chemotherapy—Sulfonamide Group.

Dr. Sumner L. S. Koch, Chicago, Tendon Suturing.

Drs. James E. M. Thomson and Charles F. Perciot, Lincoln, Neb., Fractures of the Patella.

Dr. Spencer Wright, Salt Lake City, Newer Methods for the Repair of Inguinal Hernia.

Dr. Harold Feil, Cleveland, Cardiovascular Disabilities of Railway Employees—Problems of the Consultant: A Review of Eight Years' Experience.

Dr. Elisha S. Gurdjian, Detroit, Management of Traumatic Intracranial Hemorrhage.

Drs. Samuel J. Kopetzky and Ralph Almour, New York, Otoscopy in the Inflammations; A Clinic on Petrositis.

Bureau Plans Medical Aid to China.—The American Bureau for Medical Aid to China recently voted to spend \$228,721 for immediate shipment of medical and other supplies to China. The fund was collected in part by the "Bowl of Rice" parties in California and also includes donations of \$75,000 from the national committee of United China Relief and \$45,000 from the China Emergency Relief Committee. Eight agencies carrying on relief work for China have recently combined with the joint title of United China Relief. Dr. Walter B. Cannon, Boston, is chairman and Donald D. Van Slyke, Ph.D., New York, is vice chairman of the medical division. The money will be used for support of hospitals for rehabilitation of bombed soldiers and civilians, for a first aid station for air raid victims in Chungking, for the emergency training schools for nurses and medical aides, for a medical library needed by the hospitals in their training work and for tools for transport repair shops for the Chinese Medical Relief Corps. Purchases will be made in consultation with the American Red Cross and the China Defense Supplies Commission recently established in Washington. The committee which will direct the expenditures consists of Drs. Frank Wang Co-Tui, chairman; Frank L. McLency and Edward H. Hume, and Mr. Chih Meng. All are of New York.

Foreign Letters

PARIS

(From Our Regular Correspondent)

June 15, 1941.

Epidemic of Scabies

The incidence of scabies has tripled within the last few years. In 1938, 6,194 cases were observed in the Hôpital Saint Louis. This rose to 7,914 cases in 1939 and to 24,664 in 1940. There were three periods of exacerbation, the first among the mobilized, the second in the month of June at the time of massive evacuation of the populace and the third at the return of the evacuated in August.

In 1795, during the French Revolution, military centers of treatment for scabies were organized by decree. It was one of the problems of Napoleon to determine where to evacuate those affected with scabies. The present epidemic has permitted verification of the role which the germ carriers play in the dissemination of sarcoptes. Often a member of a family, to all appearance unaffected himself, by refusing to take precautionary measures spreads the contamination. Pignot pointed out before the Academy of Medicine the need of discovering these apparently innocuous carriers. The present scarcity of soap has had a direct influence on the epidemic. Various treatments have been employed at the Hôpital Saint Louis, such as Helmerich's ointment. However, fats have become so scarce in France that ointments will soon no longer be obtainable.

Wounds of the Head

Piquet and his associates reported recently to the Academy of Surgery their experiences with craniocerebral traumas in May 1940, at the time of the German invasion. Piquet was surgeon in chief of a center for cranial surgery situated on a bank of the LaManche River, a point distant from the combat zone. On May 18 this center found itself suddenly in the midst of a battle, and men with cranial wounds were rushed in. The hospital equipment was limited, and on the 19th electricity failed them. No longer could roentgenography, surgical diathermy or wound aspiration be done. Nor could foreign bodies be located in the wounds. Most of the wounded brought in for treatment had been injured ten days or two weeks previously and had been treated, more or less promptly, in another ambulance. Piquet's center was facing appalling conditions because of the scarcity of personnel and equipment and the pressure of time. The overworked surgeons were practically forced to adopt the surgical measures of the World War. Primary suture was done only on wounded men whose injuries did not date back beyond thirty-six hours. Fortunately, the sulfanilamide supplies were sufficient and massive doses were given. Failures were partly due to the inability to carry out the measures for the discovery of foreign bodies in the brain. Fatalities occurred in one third of the cases; only one third of these could be operated on in less than forty-eight hours after wounding. An additional factor was the need of moving the injured to make room for others. Piquet believes that foreign bodies in the brain should be removed as speedily as possible. This should be followed by prompt surgical intervention, done in one stage.

Technic for Determining Bactericidal Power of Blood

Bécard and Lepeut recently described before the Society of Medicine of Paris a simplified method for determining the bactericidal power of the blood. Blood specimens are obtained by digital puncture. No citrate is added. From a mother dilution representing a titer of 25,000,000 micro-organisms decimal dilutions in concentration ratios of 1, 10, 100 and 1,000 are prepared. These decimal dilutions are placed in four tubes and carefully mixed by shaking. By means of a graduated

pipet a drop of the blood to be examined is deposited in each of the tubes and the latter incubated for thirty minutes at normal temperature (37 C.). Four different areas of the culture medium are inoculated with a drop of the dilution in a Petri dish containing peptonized agar-agar and incubated for twelve hours at normal temperature. The colonies of each area are then counted with a magnifying glass. The results are recorded in a diagram on which normal dilution figures (15, 150, 1,500, 15,000) are given on the abscissas and the bacterial count obtained from the colonies on the normal ordinates. The results are inscribed on the right or the left of the line representing the meeting place of abscissas and normal ordinates, the right indicating microbial decrease and hence a positive bactericidal power, the left indicating the opposite. The authors believe that by means of their diagram useful conclusions can be rapidly drawn regarding the surgical intervention proposed, the indications for immunotransfusion and in regard to the blood donors whose blood is highly bactericidal in view of the immunotransfusion.

Cold and Undernourishment

F. Bezançon discussed before the Academy of Medicine the dangers of undernourishment as it is affected by cold. The problem of heat regulation involves that of chemical thermoregulation and, in man, that of the peripheral circulation. Adaptation of the caliber of the blood vessels to the activity of their thermal functions varies in individuals. Urban dwellers who are not as extensively exposed to all the variations of outside temperatures lack good defense reflexes. Under the influence of cold, it is necessary for warm blooded animals to triple and quadruple the calory supply. The thermometric descent from 59 to 32 F. requires, for example, in the rat a tripling of the metabolism in relation to its basal metabolism. Aids in the process consist in shivering, in the chemical regulation of the body and in the support which the liver, the glands and the cells contribute. In human beings dwelling in our climate who do not modify a great deal the protective nature of their clothes, the thermal adjustment varies from 1,810 calories in summer to 3,000 calories with the arrival of cold.

Certain foods possess nutritional value against cold. Proteins, fats and carbohydrates may be substituted for one another to a certain extent; yet a vital minimum of each of these is indispensable. This involves the problem of equilibrium. Diets must contain protein, fat, mineral salts and amino acids. Individual physiologic differences as well as differences in the surrounding environment such as dryness, winds and sunshine are frequent. The frequent occurrence of chilblains during the recent severe cold demonstrated the role which food imbalance plays, for milk and butter are almost lacking at present in the French diet. Undernourishment, coupled with dietary imbalance, is particularly prejudicial to tuberculous persons in the developmental stage or with pneumothorax and to those affected with grave anemia. Physicians are now authorized to demand increased food allocations for persons with these disorders.

Psittacosis

Psittacosis has made its appearance in the Paris area. Fearing that the disease might spread, the public health department has made it notifiable. Psittacosis was first reported in Europe in 1930. The importation of parrots to France was prohibited at the time, and the bird shops were subjected to special inspections. In spite of these precautions, psittacosis did not altogether disappear. Isolated cases were encountered every year. Epidemiologic inquiries showed that these were due to the contamination of native breeding places. The source of these sporadic infections could not be traced, but it is now well

known that interhuman contamination is quite frequent. Diagnostic methods have been developed, but physicians in general often confuse the manifestations of psittacosis with those of influenza. Sacquépée, discussing this subject before the Academy of Medicine, believes that, if diagnosis was more searching, more cases of psittacosis would be found.

Congenital Dilatation of the Pulmonary Artery

Laubry and Routier recently reported to the Academy of Medicine their findings in 39 cases of a condition which they regard as congenital dilatation of the pulmonary artery but which Cossio of Buenos Aires had described clinically and roentgenologically as interauricular communication. Eight of their cases came to necropsy. The symptomatology is diverse, yet the roentgenologic signs are constant enough and similar to those disclosed in the roentgenogram to permit grouping them together. The description of the roentgenologic silhouette shows a significant right border, an arc of average projection, strongly expansive pulmonary hilus shadows and a smaller invisible aortal semicircle. Clinically, diastolic and systolic murmurs were noted. Functional signs, especially cyanosis, were delayed. The evolutionary trend was generally toward bronchial dilatation, to chronic emphysema with thoracic blockage or toward pulmonary tuberculosis.

RIO DE JANEIRO

June 15, 1941.

Cardiovascular Diseases in Rio de Janeiro

The cardiovascular diseases offer considerable difficulty in an appraisal of their importance, because many of the factors involved are ignored. In Rio de Janeiro exact studies on the incidence of these diseases have been lacking, though mortality statistics have been kept since 1903, which year marked the beginning of the modern era of public health in Brazil. Publication of the mortality data for the last fifteen years has shown that deaths from cardiovascular diseases increased from 9.41 per cent of the deaths from all causes in the period 1926-1930 to 11.37 per cent in the period 1936-1940, and the crude specific death rate similarly increased from 165 to 189 per hundred thousand of population, an increase of 14.54 per cent.

More interesting is the study of the morbidity by Prof. Pedro Da Cunha of the Fluminense Medical School and the Gaffrée-Guinle Hospital, relating to 40,186 people attending the outpatient clinic of that hospital from 1926 to 1939. Of this total, 32,830 patients, or 81.70 per cent, were classified as afflicted by diseases of the cardiovascular system. The patients were 37.74 per cent male and 62.26 per cent female, 80.17 per cent of Brazilian nationality and 19.83 per cent foreign, 64.16 per cent white and 35.89 per cent Negro, 31.26 per cent single, 54.74 per cent married and 14.00 per cent widowed and divorced, 7.68 per cent under 20 years of age, 76.99 per cent between 20 and 49 and 16.43 per cent 50 years and over. The aneurysms are only 0.40 per cent of the grand total. Some features of the study need emphasis. Essential hypertension has been found in only 0.29 per cent of the cases and hypotension in 0.45 per cent. Syphilis was the cause of cardiovascular disease in 24 per cent of the patients, and in about two thirds the specific lesion was in the aorta. Syphilis was much more frequent as a cause of valvular diseases than rheumatic conditions. The ratio between syphilis and rheumatism is about 2:1 for the aortic lesions and about 1:1 for the mitral lesions. The Wassermann reaction was positive in 24.95 per cent of the cases of aortic lesions and in 22.75 per cent of the mitral lesions. Rheumatic conditions alone were found in 10.80 per cent of the cases, and in 2.20 per cent associated with syphilis. As a probable explanation, Rio de Janeiro has a tropical climate, where rheumatic diseases are rather rare and syphilis is very prevalent.

It is interesting to note at the same time the principal features of a report by Dr. Amadeu Fialho, pathologist of the public health laboratory of the city, on the results of 3,474 necropsies in which 890 cases of cardiovascular diseases were found. Of the 890 deaths attributed to cardiovascular diseases, atherosclerosis accounted for 322 cases, cardiac hypertrophy for 168, diseases of the pericardium for 81, syphilitic aortitis for 70, valvular diseases for 69, endocarditis for 63, aneurysm of the thoracic aorta for 40 and sclerosis of the myocardium for 10.

Still another contribution on the subject is that of Drs. Aloysio De Paula and Francisco Benedetti, who examined, in the Health Centers of Rio de Janeiro, 28,293 office and shop employees with the use of the miniature roentgenogram and found unknown cases of heart disease in 0.8 per cent, and unknown aortic disease in 3.9 per cent.

Marriages

CHARLES WHITE MILLENDER, Asheville, N. C., to Miss Dorothy Thompson Aiken of Columbia, Tenn., recently.

WILLIAM CHESTER, Mamaroneck, N. Y., to Miss Anne Mitsak of Bridgeport, Conn., in New York, May 24.

JOHN MILTON STRAIT JR., Columbus, Ohio, to Miss Anne Louise Ferguson of Mount Vernon, June 19.

ROBERT McCLELLAN JAMES, Louisville, Ky., to Miss Lois Livingston of Hazard in Covington, June 14.

ALVA DUCKETT DAUGHTON, East Falls Church, Va., to Miss Vera Alice Hanson of Richmond, July 18.

HAROLD RAWLING PRATT-THOMAS to Miss Mary Porcher Douglas, both of Charleston, S. C., July 2.

GEORGE ASHBY WINSTEAD to Miss Jacqueline Gainer Denson, both of Rocky Mount, N. C., June 17.

FRANCIS PATRICK O'LINN, Youngstown, Ohio, to Miss Margaret Ellen Rataiczak of Troy, June 28.

JOHN WASHINGTON CLARK, Front Royal, Va., to Miss Sallie McArthur Mason of Ridgeway, June 24.

MAURICE J. SMALL, Parsons, W. Va., to Miss Sylvia Cantor of New Rochelle, N. Y., March 25.

WILLIAM CARLETON SMITH, Lockhart, Texas, to Miss Maybell Hardie of Fort Worth recently.

WALDEMAR RICHARD AGRICOLA to Miss Virginia Berry, both of Newcomerstown, Ohio, in July.

NORMAN DOUGLAS ELLIS JR., Martin, S. C., to Miss Martha Alice Bennett of Dillon, June 28.

BENJAMIN FRANKLIN HOOPES, Bloomington, Ill., to Miss Frances Kelly of Chicago recently.

SAMUEL JOSEPH CAMPBELL, Bucyrus, Ohio, to Miss Dorothy Isabel Cole in Fremont, June 21.

WILLIAM ST. JULIEN JERVEY to Miss Susan Amelia Sprague, both of Tryon, N. C., June 30.

WILLIAM HENRY BANDY, Lincolnton, N. C., to Miss Pauline Pope of Linwood, June 21.

HUGH I. CONN, Newman, Ill., to Miss Virginia Thompson at Danville, Ind., June 12.

RUSSELL C. LONG, Zanesville, Ohio, to Miss Isabel Hepler of Mount Vernon in June.

GILBERT THOMAS RANSOM to Mrs. Robley Wilson, both of Fairfield, Ill., in June.

HARLIN G. KNIERIM, Detroit, to Miss Florence Stevens of Galion, Ohio, recently.

ABRAHAM W. FELDMAN to Miss Minerva Shapiro, both of Chicago, August 10.

SOL L. LOWENSTEIN to Miss Corinne Cohn, both of Nashville, Tenn., July 2.

STANLEY H. MACHT, Crewe, Va., to Miss Naomi Newman of Danville, July 1.

PAUL AXTELL BUNN, Cleveland, to Miss Elizabeth Maxwell of Akron, June 14.

Deaths

John Price Crozer Griffith * Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1881; emeritus professor of pediatrics at his alma mater and the *Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania*; member of the American Pediatric Society; for many years treasurer of the Association of American Physicians; past president of the Philadelphia Pediatric Society; corresponding member of the Société de pédiatrie de Paris; served at various times and in various capacities on the staffs of St. Christopher's Hospital for Children, Children's Hospital, Women's Hospital, Jewish Hospital, Abington (Pa.) Memorial Hospital, Misericordia Hospital and the Babies Scares Hospital; author of several volumes on children's diseases; aged 85; died, July 28, at his summer home in Devon.

Edward Frankel Jr. * New York; Columbia University College of Physicians and Surgeons, New York, 1905; instructor in otolaryngology at his alma mater from July 1, 1930 to June 30, 1932; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; past president of the American Stomatological Association; veteran of the Spanish-American and World wars; on the staffs of the Broad Street Hospital and the Presbyterian Hospital; associate editor of the *Journal of Dental Research* from 1932 to 1937; aged 60; died, July 3, of embolism following an appendectomy.

Frederick Eugene Hopkins * Springfield, Mass.; University of the City of New York Medical Department, 1884; member of the American Laryngological Association and the American Laryngological, Rhinological and Otolological Society; past president of the New England Otolological and Laryngological Society; fellow of the American College of Surgeons; for many years member of the school committee; at various times on the staff of the Springfield Hospital, Noble Hospital, Westfield and the Memorial Hospital, Brattleboro, Vt.; aged 83; died, July 1, of cerebral embolism and hypertrophy of the prostate.

Edmund Sheppard Ferguson * Oklahoma City; Detroit College of Medicine, 1895; emeritus professor of ophthalmology at the University of Oklahoma School of Medicine; one of the founders and past president of the Oklahoma City Academy of Medicine; past president of the Oklahoma State Medical Association; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; on the staffs of St. Anthony's, Wesley and Oklahoma City General hospitals; aged 70; died, June 28, of coronary occlusion.

Frank Everett Kittredge * Nashua, N. H.; University of Pennsylvania Department of Medicine, Philadelphia, 1885; member of the American Academy of Ophthalmology and Otolaryngology and American Laryngological, Rhinological and Otolological Society; past president of the New England Otolological and Laryngological Society; fellow of the American College of Surgeons; on the staffs of St. Joseph's and Nashua hospitals; aged 79; died, July 8, of heart disease in Newfoundland while on a fishing trip.

Caspar W. Sharples * Seattle; University of Pennsylvania Department of Medicine, Philadelphia, 1888; member of the Pacific Coast Surgical Association and past president of the North Pacific Surgical Association; fellow of the American College of Surgeons; past president of the city school board; past president of the Washington State Medical Association; on the staff of the Children's Orthopedic Hospital; aged 75; medical superintendent of the Seattle General Hospital, where he died, July 15.

William Hurley Strietmann * Oakland, Calif.; Medical College of Ohio, Cincinnati, 1905; at one time instructor in obstetrics and demonstrator of physiology at his alma mater; fellow of the American College of Physicians; past president of the Alameda County Medical Society; member of the Alameda County Institutions Commission; chairman of the medical department of the Alameda County Hospital; on the staff of the Peralta Hospital; aged 60; died, July 14, of coronary disease.

George Kingsley Olmsted * Denver; Denver and Gross College of Medicine, 1903; past president of the state board of health; fellow of the American College of Physicians; on the staffs of the Denver General and St. Luke's hospitals; lieutenant colonel, medical reserve corps, United States Army, retired; aged 69; died, June 25, in St. Luke's Hospital of coronary thrombosis and diabetes mellitus.

Willard Clifton Hearin, Greenville, S. C.; Medical Department of Tulane University of Louisiana, New Orleans, 1910; member of the South Carolina Medical Association and the South Atlantic Association of Obstetricians and Gynecologists; past president of the Greenville County Medical Society; served during the World War; aged 54; died, July 9, in St. Francis Hospital of angina pectoris.

John Bell, New Glasgow, N. S., Canada; McGill University Faculty of Medicine, Montreal, Que., 1898; for many years secretary of the Pictou County Medical Association; for many years a member of the legislative council of Nova Scotia; on the staff of the Aberdeen Hospital; aged 65; died, May 27, in the Victoria General Hospital, Halifax.

John Purney, New Britain, Conn.; Baltimore Medical College, 1906; member of the Connecticut State Medical Society; served with the Canadian Army during the World War; on the staff of the New Britain Hospital; aged 62; died, July 18, of coronary thrombosis while on his vacation in Shelburne, Nova Scotia, Canada.

Rollin M. Pelton, Richford, Vt.; University of Vermont College of Medicine, Burlington, 1888; member of the Vermont State Medical Society; for many years member of the school board and health officer; formerly member of the state legislature; aged 75; died, June 4, in the Mary Fletcher Hospital, Burlington, of arteriosclerosis.

Aaron A. McKelvey, Van Buren, Ark.; Arkansas Industrial University Medical Department, Little Rock, 1894; member of the Arkansas Medical Society; formerly a member of the Veterans Administration; city and county health officer; aged 74; died, May 21, in a hospital at Fort Smith of heart disease.

Bernard Rubenstein * Dallas, Texas; Baylor University College of Medicine, Dallas, 1922; assistant professor of clinical gynecology at his alma mater; fellow of the American College of Surgeons; on the staffs of the Parkland and Baylor hospitals; aged 51; died, June 12, of coronary occlusion.

John Glasscock Tye, Barbourville, Ky.; University of Louisville Medical Department, 1909; member of the Kentucky State Medical Association; member of the board of health; aged 60; died, June 21, in the Kentucky Baptist Hospital, Louisville, of carcinomatosis.

John Edward Lawrence Walsh, Evanston, Ill.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1886; Rush Medical College, Chicago, 1887; aged 79; died, July 1, in St. Luke's Hospital, Chicago, of coronary thrombosis and carcinoma of the stomach.

Cleal Giles Hissong, Hamler, Ohio; Eclectic Medical College, Cincinnati, 1915; member of the Ohio State Medical Association; mayor; served during the World War; member of the board of education; aged 50; died, June 29, of coronary thrombosis.

Chauncey Goodrich Wright, St. Louis; Washington University School of Medicine, St. Louis, 1905; member of the Missouri State Medical Association; served during the World War; aged 67; died, June 10, in the Missouri Baptist Hospital.

Thomas Gibson, Kingston, Ont., Canada; University of Edinburgh Faculty of Medicine, Scotland, 1894; professor of the history of medicine, Queen's University Faculty of Medicine; aged 75; died, July 2, in the Kingston General Hospital.

Bertha Wagner Stark, Los Angeles; Hahnemann Medical College of the Pacific, San Francisco, 1895; College of Physicians and Surgeons of San Francisco, 1901; aged 76; died, June 28, in San Bernardino of acute dysentery.

Jacob Moon Anderson, Sardis, Miss.; Memphis (Tenn.) Hospital Medical College, 1898; member of the Mississippi State Medical Association; town health officer; past president of the school board; aged 71; died, July 8.

Joseph Fulgence Archambault, West Warwick, R. I.; College of Physicians and Surgeons, Baltimore, 1905; member of the Rhode Island Medical Society; aged 60; died, June 26, in Bridgton, Maine, of coronary thrombosis.

John Lewis Bishop, Niagara Falls, N. Y.; University of Buffalo School of Medicine, 1903; served during the World War; formerly city health officer; aged 64; died, June 10, in the Memorial Hospital of coronary sclerosis.

Josie C. Kennedy Diederich, Rochelle, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901; member of the Illinois State Medical Society; aged 68; died, June 7.

Clifford Sater, Cincinnati; Miami Medical College, Cincinnati, 1901; served during the World War; aged 70; died.

June 28, in San Diego, Calif., of hypostatic pneumonia, diabetes mellitus and fracture of the femur.

Frank William Knittel @ Brunswick, Ohio; St. Louis University School of Medicine, 1928; on the staff of the Community Hospital, Berea; aged 40; died, June 26, of injuries received in an automobile accident.

John Whitworth Harrison, Kansas City, Mo.; Medical Department of Tulane University of Louisiana, New Orleans, 1899; veteran of the Spanish-American War; aged 64; died, June 10, of chronic myocarditis.

William Henry Haines, Audubon, N. J.; Jefferson Medical College of Philadelphia, 1912; served during the World War; for many years member of the city board of health; aged 55; died, July 5, of heart disease.

Hjalmar V. Barclay, Corona, N. Y.; University of the City of New York Medical Department, 1893; aged 81; died, June 23, in the Roosevelt Hospital, New York, of arteriosclerosis and heart disease.

Joseph Alan Corson, Wilkes-Barre, Pa.; Jefferson Medical College of Philadelphia, 1921; member of the Medical Society of the State of Pennsylvania; aged 46; died, May 25, of cerebral hemorrhage.

James Clair Ash, Lake Andes, S. D.; Barnes Medical College, St. Louis, 1899; member of the South Dakota State Medical Association; formerly member of the state legislature; aged 70; died in July.

Albert C. McClanahan @ Los Angeles; Rush Medical College, Chicago, 1889; member of the Colorado State Medical Society; aged 76; died, June 15, at Santa Barbara, Calif., of coronary thrombosis.

U. S. Grant Sparks, Pitman, N. J.; Medico-Chirurgical College of Philadelphia, 1895; aged 68; died, May 26, in the New Jersey State Hospital, Trenton, of coronary occlusion and arteriosclerosis.

Constantine A. Carusos, New York; National University of Athens School of Medicine, Greece, 1902; aged 58; died, June 8, in Tarpon Springs, Fla., of cerebral hemorrhage and heart disease.

Fred Hugh Van Tassell, Oakland, Calif.; University of California Medical Department, San Francisco, 1904; aged 62; died, June 29, in the Berkeley (Calif.) Hospital, of cerebral hemorrhage.

Fred Clark Taylor @ Peru, Ill.; Medical College of Indiana, Indianapolis, 1894; aged 68; on the staff of the People's Hospital, where he died, June 29, of peritonitis following an operation.

Dallas Curtice Johnson, San Antonio, Texas; University of Texas School of Medicine, Galveston, 1926; served during the World War; aged 43; died, June 24, of pulmonary tuberculosis.

George Byron Walrath, Los Angeles; University of Southern California College of Medicine, Los Angeles, 1895; aged 75; died, June 20, of carcinoma of the pyloric end of the stomach.

Thomas Ives Byrne, Yarmouth, N. S., Canada; Bellevue Hospital Medical College, New York, 1894; for many years deputy minister of health of Nova Scotia; aged 67; died, May 29.

George Augustus Porter Boulden, Staten Island, N. Y.; Long Island College Hospital, Brooklyn, 1897; aged 78; died, May 12, in Montgomery township, N. J., of chronic myocarditis.

Ernest Franz, Berne, Ind.; Hahnemann Medical College and Hospital, Chicago, 1893; member of the Indiana State Medical Association; aged 76; died, June 27, of cerebral hemorrhage.

Felton D. Watts, Portland, Ore.; Detroit College of Medicine, 1904; member of the Oregon State Medical Society; aged 75; died, June 17, of coronary occlusion and hypertension.

Charles Anthon Walters, Santa Fe, Tenn.; University of Tennessee Medical Department, Nashville, 1896; served during the World War; aged 70; died, June 10, of myocarditis.

Thomas James Gallagher, Paterson, N. J.; Temple University School of Medicine, Philadelphia, 1923; aged 47; died, June 30, in St. Joseph's Hospital of coronary occlusion.

Abel W. Truesdell, Lake Orion, Mich.; Saginaw (Mich.) Valley Medical College, 1902; for many years health officer; aged 83; died, June 28, of carbolic acid taken accidentally.

Edward Lipman Efroymsen, Bell, Calif.; Indiana University School of Medicine, Indianapolis, 1935; aged 30; died, June 12, of an overdose of a sedative, self administered.

George L. Brooks @ Chicago; Chicago Homeopathic Medical College, 1901; on the staff of the Chicago Memorial Hospital; aged 62; died, July 2, of coronary occlusion.

Raymond James Stoup @ Syracuse, N. Y.; Syracuse University College of Medicine, 1900; aged 63; died, June 11, in the University Hospital of myelogenous leukemia.

John Wesley Newlove, Los Angeles; Detroit College of Medicine, 1902; served during the World War; aged 61; died, June 29, of cirrhosis of the liver and edema.

William Rice Silverstein, Bradley Beach, N. J.; Baltimore Medical College, 1903; aged 58; died, June 21, in the Beth Israel Hospital, Newark, of cholelithiasis.

Bertha Olive Anderson @ Pittsfield, Mass.; University of Kansas School of Medicine, Kansas City, Kan., 1911; aged 58; died, June 25, of coronary thrombosis.

Gustav Baar, Portland, Ore.; Medizinische Fakultät der Universität Wien, Austria, 1897; aged 68; died, July 6, of hypertensive cardiovascular disease.

John Henry Weckel, Syracuse, N. Y.; University of the City of New York Medical Department, 1879; aged 83; died, June 30, of cerebral hemorrhage.

John J. Johnson, Harrison, Ark.; Marion-Sims College of Medicine, St. Louis, 1896; member of the Arkansas Medical Society; aged 80; died in June.

Calbert H. Beach, Glencoe, Okla.; Missouri Medical College, St. Louis, 1889; Barnes Medical College, St. Louis, 1898; aged 79; died, May 15.

Ella Pearson Sumner, Hastings, Neb.; Omaha Medical College, 1895; member of the Nebraska State Medical Association; aged 94; died, June 10.

James M. Tyson, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1892; aged 79; died, June 13, of cerebral thrombosis.

Michael Joseph Donovan, Perry, Iowa; John A. Creighton Medical College, Omaha, 1907; aged 68; died, June 12, of coronary thrombosis.

Harvey James Clements @ Salem, Ore.; New Orleans University Medical College, 1892; aged 72; died, June 25, of coronary occlusion.

Thomas P. Mitchell, Lincolnton, Ga.; University of Georgia Medical Department, Augusta, 1887; aged 88; died, April 9, of mitral insufficiency.

William Wallace Aldrich, Wevertown, N. Y.; Dartmouth Medical School, Hanover, N. H., 1878; aged 87; died, June 24, of arteriosclerosis.

Hubert Adolphus Thomas, Princeton, Ky.; Meharry Medical College, Nashville, Tenn., 1930; aged 41; died, June 17, of acute endocarditis.

Ralph Milburn Burton @ Toledo, Ohio; University of Louisville (Ky.) School of Medicine, 1925; aged 41; died, June 23, of carcinoma.

William H. Buchan, Gilmer, Texas; Memphis (Tenn.) Hospital Medical College, 1902; aged 63; died, June 2, of chronic nephritis.

Laurence Victor Croft, London, Ont., Canada; McGill University Faculty of Medicine, Montreal, Que., 1903; aged 64; died, May 19.

John Donald Stewart, Calgary, Alta., Canada; McGill University Faculty of Medicine, Montreal, Que., 1911; aged 56; died, May 23.

Ernest Sullivan, Oklahoma City; Barnes Medical College, St. Louis, 1907; aged 59; was found dead in bed, June 1, of heart disease.

Mark Hilton Moore, Athens, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1903; aged 68; died, May 26.

Frederick E. Dillenbeck, El Dorado, Kan.; University Medical College of Kansas City, Mo., 1896; aged 74; died, June 5.

Douglas Hart, Montgomery, Ind.; Louisville (Ky.) Medical College, 1891; aged 80; died, July 1, of carcinoma of the face.

Squire H. Redmon, Tipton, Mo.; St. Louis Medical College, 1880; aged 87; died, May 7, of chronic interstitial nephritis.

Albert David Faust, Bala-Cynwyd, Pa.; Jefferson Medical College of Philadelphia, 1894; aged 69; died, June 9.

Linton S. Archer, Atlanta, Ga.; Maryland Medical College, Baltimore, 1908; aged 57; died, July 4.

Bureau of Investigation

THE MACHINE AGE MOVES IN ON SEX Contraption Promoted as Sexual Cure-All Declared Fraudulent

For many years mechanical devices and nostrums have been the subjects of United States Post Office fraud orders. During recent years this department of THE JOURNAL has given little space to what, for want of a better term, are called "sex frauds"—that is, those devices and "cures" promoted solely for the treatment of imaginary or real sexual deficiencies.

Now the Post Office Department has issued a fraud order against a concern which promoted a mechanical device like something out of Dr. Seuss or Rube Goldberg. Under the names Grindley and Company and Matrimonial Body Support Company, Missoula, Mont., one Thomas C. Grindley advertised and sold through the mails a booklet entitled "A Positive Solution to Many of the Problems of Coitus in Married Life." The memorandum of charges served by the Post Office Department on Mr. Grindley alleged that the following pretenses, representations and promises were false and fraudulent: That the booklet correctly advises how to restore "strength, pep, vitality and endurance" to sexually weak men, regardless of age or physical condition; that it advises how effectively to correct "premature ejaculation"; that it correctly advises purchasers how to continue the sexual act with perfect satisfaction for an hour or more and maintain an erection of the male sexual organ during that time; that the booklet correctly advises purchasers how to retard the climax of the sexual act as long as desired "without fatigue," and how to perform the sexual act "as often as desired" and leave the user "fresh as a daisy afterward"; further, that it advises how to prevent "frigidity" in women and furnishes effective information on "birth control."

Examination of the text of the booklet shows that the results mentioned were to be obtained by the construction of a device designed to support the weight of the male during the act of coitus. This extraordinary construction was to be made by the purchasers of the booklet according to the specifications set forth in the last four pages. According to the fraud order, "it consists of two metal braces, to be placed approximately two feet apart, connected by a metal rod, suspended from which is a heavy canvas or linen upon which the body of the male is to be placed during the act of sexual intercourse. For those who do not wish to make their own support as described in the booklet, the promoter offers to make one and furnish the same for prices ranging from \$3.50 to \$4.00."

Also included in the booklet are the following directions:

HOW TO USE

Be sure that the cross or tie bar marked "O" clears the body of the woman by at least one inch (below the breasts) when the entire weight of the man is upon the support.

Next get into position and adjust the edge of the fabric support so that it is just above the woman's pelvis, and supports the entire abdomen of the man.

Then tilt the fabric support so that the man's weight is barely raised off the woman's abdomen. One adjustment is generally final.

Do not cut down the strength of the materials suggested. The support has to be strongly made. Use 10 ounce canvas or very strong linen, re-enforced to make fabric support.

The picture of the human animal endeavoring to propagate the species while at the same time manipulating this combination hoist and viaduct is something that startles the imagination. Expert testimony of government witnesses was nevertheless apparently necessary to show the wide variety of etiologic factors of the various disorders which this device was claimed to correct. It was so obviously a scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises that the Solicitor recommended that a fraud order be issued. The Acting Postmaster-General on April 30, 1941 issued Order No. 15486 against Grindley and Company, the Matrimonial Body Support Company and their officers and agents as such.

Correspondence

HEMOGLOBIN-RED BLOOD CELL RATIO

To the Editor:—In an article entitled "A Simple Hemoglobin-Red Blood Cell Ratio to Replace the Color Index" (THE JOURNAL, May 17, p. 2258) Isaacs criticizes the value of the color index figure of the blood. He states: "However, the lack of single 'normal' figures for the percentage of hemoglobin and red blood cell counts, as well as the differences in males and females, has always made the number somewhat arbitrary. With the advent of hemoglobinometers in which 100 per cent corresponds to 13.5, 14, 15.6 or 17 Gm., the problem is further complicated by the difference in readings of the percentages."

These statements indicate that Isaacs' method of determining the color index does not conform to that commonly employed, and because it may lead to further confusion the statements should be corrected. The color index is determined by dividing the percentage of the normal hemoglobin value calculated from the hemoglobin reading obtained by the percentage of the normal erythrocyte level calculated from the erythrocyte count obtained. Consequently it makes no difference whether the patient is male or female or what number of grams of hemoglobin corresponds to 100 per cent on the hemoglobinometer reading.

It is true that there is some slight divergence of opinion in regard to what the normal hemoglobin and erythrocyte levels are for male and female patients and at various ages, but these differences will affect the final calculation little. If one assumes that the average normal hemoglobin and erythrocyte levels are 15.5 Gm. and 5,200,000 for males and 14.5 and 4,800,000 for females, one may readily see that the normal color index in each case is 1; that is, 100 per cent/100 per cent = 1. In each case, each figure represents 100 per cent of normal irrespective of the sex or, in the case of the hemoglobin figures, what amount of hemoglobin corresponds to 100 per cent on the scale used.

To illustrate, using Isaacs' figures: 9.3 Gm. of hemoglobin is 60 per cent of the normal male ($9.3/15.5 \times 100 = 60$ per cent) and 64.2 per cent of the normal female ($9.3/14.5 \times 100 = 64.2$ per cent) hemoglobin; 2,800,000 erythrocytes per cubic millimeter is 53.8 per cent of the normal male ($2,800,000/5,200,000 \times 100 = 53.8$) and 58.4 per cent of the normal female ($2,800,000/4,800,000 \times 100 = 58.4$) erythrocyte level. Therefore, $60/53.8 = 1.11$ color index for the male and $64.2/58.4 = 1.10$ color index for the female. To carry the calculations further, Isaacs uses the same erythrocyte level with 7 Gm. of hemoglobin. Calculations made in the same manner show color index values for the male $45.2/53.8 = 0.84$ and for the female $48.2/58.2 = 0.83$. It is obvious from these figures, readily computed on the slide rule, that in the first example the color index is approximately 1, whereas in the second example it is below normal, indicating an iron deficiency whether or not the patient is male or female and without reference to the percentage reading obtained from the hemoglobinometer used. This is an excellent example of the desirability of reporting hemoglobin values in grams rather than in percentage unless the number of grams represented by 100 per cent is stated. When this is done, there should be no confusion in regard to the hemoglobin content or the color index figure in any specimen of blood. Present day means available for determining the hemoglobin and erythrocyte levels are far superior to those in use a few years ago, so that greater accuracy is possible, thus making the color index figure a much more reliable and valuable one than it was a few years ago.

WILLIAM P. MURPHY, M.D., Boston.

[NOTE.—The preceding letter was referred to Dr. Isaacs, who replies:]

To the Editor:—Dr. Murphy assumes that the average "normal" hemoglobin and erythrocyte levels are 155 Gm and 5,200,000 for males and 145 Gm. and 4,800,000 for females. This illustrates my point exactly and demonstrates just what I wished to avoid. These standards of normal (1) are purely arbitrary and (2) differ with different workers and authors and in different parts of the country. I certainly agree with Dr. Murphy that the reporting of hemoglobin in grams is more desirable than in percentage, and my formula was merely a way by which a physician without a slide rule could get a mental image of whether the number of grams was high, low or comparable to the changes in the individual patient's red blood cell count. It is easy to multiply the number of grams of hemoglobin by 3 and see whether this number is higher than, equal to or lower than the first two figures of the red blood cell count.

RAPHAEL ISAACS, M.D., Chicago.

PRESCRIPTION OF SULFONAMIDES

To the Editor:—Do you not think a warning on the unjustifiable, promiscuous and indiscriminate prescribing of the sulfonamides in an effort to curb such unwarranted practice might be timely and perhaps serve a good purpose?

A few years ago at a general medical meeting I was the only otolaryngologist of three present who spoke against such practice. The other two and many general practitioners said that they prescribed sulfonamide derivatives as a routine in the home in every case of acute suppurative otitis media. I decried it then, and all the more do I do so now after two years have passed and I have seen the results.

Only yesterday I had a typical example of their misuse—and this is not an isolated case: A woman aged 20 had acute suppurative otitis media with a spontaneous perforation on June 15, 1941. The next day her otologist placed her on sulfanilamide 2 tablets every four hours for twenty-five doses. The ear discharged freely for about two weeks and then stopped, with return of the otalgia. Her otologist performed a myringotomy, following which the ear again discharged freely until July 13, when it stopped with return of pain, and when I saw her for the first time on the evening of July 15 she had advanced acute mastoiditis. I did a mastoidectomy on her the next day. The whole mastoid was filled with pus and granulations, and there was a small fistula through the outer table. Necrosis of the bone was far advanced and the dura was exposed and bathed in pus. It was evident that mastoiditis had existed for some time, the symptoms masked by sulfanilamide, and if it had not perforated through the outer mastoid wall meningitis, an extradural abscess or a septic sinus thrombosis would have developed all unsuspected.

For the more than thirty years during which I have practiced otology before the advent of the sulfonamides I have seen 80 per cent of patients with acute suppurative otitis media get well without chemotherapy. If sulfanilamide is used, it should be saved for those patients who show after perhaps a week following the opening of the tympanum that they are not doing well. Then it should be given to the proper blood concentration and under such supervision that daily examinations of the blood can be made and should be continued in modified dosage for one week after all symptoms have subsided.

Why subject this 80 per cent needlessly to a toxic drug with its attendant dangers, often given in inadequate doses without proper supervision and stopped all too soon? More often than not, it does more harm than good. It would seem that the time has come when the indiscriminate, unwarranted and pernicious use of this drug should be stopped.

GEORGE W. STIMSON, M.D., Warren, Ohio.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

CHICAGO, Feb. 16-17, 1942. Council on Medical Education and Hospitals, Sec., Dr. William D. Cutter, 535 North Dearborn Street, Chicago.

BOARDS OF MEDICAL EXAMINERS

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL, August 16, page 554.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS. Parts I and II. Various centers, Sept. 15-17. Part III, Baltimore and New York City, October; Boston, November. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written*. Nov. 3. Final date for filing application is Sept. 23. *Oral*. Dec. 12-13. Final date for filing application is Nov. 8. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written*. Oct. 20. Final date for filing application is Sept. 1. *Oral*. April, in advance of the meeting of the American College of Physicians and June, in advance of the meeting of the American Medical Association. Final date for filing application is Oct. 20. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written*. Part I. Group B. Various centers, Jan. 3. Final date for filing application is Oct. 6. *Oral*. Part II. Groups A and B. Atlantic City, May or June. Final date for filing application is March 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

AMERICAN BOARD OF OPHTHALMOLOGY: *Oral*. Chicago, Oct. 18. *Written*. March 7. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Washington, January. Final date for filing application is Nov. 1. Sec., Dr. Guy A. Caldwell, 3503 Prytania St., New Orleans, La.

AMERICAN BOARD OF PEDIATRICS: *Oral*. Philadelphia, March or April, at the time of the Region I meeting of the American Academy of Pediatrics. Cleveland, May, at the time of the Region III meeting of the American Academy of Pediatrics. Los Angeles, May, at the time of the Region IV meeting of the American Academy of Pediatrics. *Written*. Locally, approximately 6 weeks in advance of the date of oral examination. Sec., Dr. C. A. Aldrich, 707 Fullerton Ave., Chicago.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: *Oral*. New York, Dec. 19-20. Final date for filing application is Oct. 6. Sec., Dr. J. Stewart Rodman, 2200 Broadway, New York.

AMERICAN BOARD OF SURGERY: *Written*. Various centers, December. *Oral*. Chicago, February. Final date for filing application is Nov. 1. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

Maine March Report

The State of Maine Board of Registration of Medicine reports the written examination for medical licensure held at Portland, March 11-12, 1941. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Twenty candidates were examined, 13 of whom passed and 7 failed. Two physicians were licensed to practice medicine by reciprocity and 4 physicians so licensed on endorsement of credentials of the National Board of Medical Examiners. The following schools were represented.

School	PASSED	Year Grad.	Per Cent
Rush Medical College	(1940)	83	
Boston University School of Medicine ..	(1940)	80	
Harvard Medical School	(1940)	80, 81	
Tufts College Medical School	(1933) 75 6, (1940)	78	
University of Pennsylvania School of Medicine	(1939)	82	
Laval University Medical Faculty, Montreal ..	(1909)	75 4	
McGill University Faculty of Medicine ..	(1940)	78	
Medizinische Fakultät der Universität Wien ..	(1929) 76, (1938)	75 3	
Faculté Française de Médecine de l'Université de St. Joseph, Beyrouth ..	(1936)	83	
Universität Bern Medizinische Fakultät	(1936)	76	
School	FAILED	Year Grad.	
Boston University School of Medicine	(1936)		
Tufts College Medical School ..	(1935)

School	LICENSED BY ENDORSEMENT	Year Grad.
Northwestern University Medical School.....	(1940)	
Duke University School of Medicine.....	(1934)	

New Mexico April Report

The New Mexico Board of Medical Examiners reports the written examination for medical licensure held at Santa Fe, April 14-15, 1941. The examination covered 12 subjects and included 100 questions. An average of 75 per cent was required to pass. Two candidates were examined, both of whom passed. Eighteen physicians were licensed-to practice medicine by reciprocity. The following schools were represented:

School	PASSED	Year Grad.
Yale University School of Medicine.....	(1930)	
Northwestern University Medical School.....	(1941)	

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Arkansas School of Medicine.....	(1939, 2)		Arkansas
Northwestern University Medical School.....	(1906)		Wisconsin,
(1929) Iowa			
Rush Medical College.....	(1926)		Illinois
University of Illinois College of Medicine.....	(1930), (1936)		Illinois
State University of Iowa College of Medicine.....	(1933)		Iowa
Kansas Medical College, Medical Department of Washburn College.....	(1904)		Texas
New York Homeopathic Medical College and Hospital.....	(1894)		New York
Ohio State University College of Medicine.....	(1923)		Ohio
University of Oklahoma School of Medicine.....	(1938)		Oklahoma
Hahnemann Medical College and Hospital.....	(1909)		Penna.
University of Pittsburgh School of Medicine.....	(1919)		Penna.
Vanderbilt University School of Medicine.....	(1936)		Tennessee
Baylor University College of Medicine.....	(1940)		Texas
Medical College of Virginia.....	(1915)		W. Virginia

Colorado June Report

The Colorado State Board of Medical Examiners reports the written examination for medical licensure held at Denver, June 10-12, 1941. The examination covered 8 subjects and included 68 questions. An average of 75 per cent was required to pass. Forty-one candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Medical Evangelists.....	(1941)*	81.5, 84.8, 87.3	
University of Colorado School of Medicine.....	(1941)	81.8,	
82, 82.3, 82.5, 83, 83, 83.3, 83.3, 84, 84.3, 84.3,			
84.3, 84.3, 84.3, 84.8, 85, 85, 85, 85.3, 85.5, 85.5,			
85.8, 85.8, 86, 86, 86.3, 86.3, 86.3, 86.5, 87, 87, 87,			
87.8, 88, 88, 88.3			
University of Oklahoma School of Medicine.....	(1940)	86	

* These applicants have completed four years' medical work and will receive the M.D. degree on completion of internship.

Maryland Homeopathic June Report

The Homeopathic Board of Medical Examiners of the State of Maryland reports the written examination for medical licensure held at Baltimore, June 24-25, 1941. The examination covered 9 subjects and included 70 questions. An average of 75 per cent was required to pass. Seven candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Hahnemann Medical Coll. and Hosp. of Philadelphia.....	(1940)	80,	
84, 86, 88, 90, (1941) 80, 82			

Oklahoma Reciprocity Report

The Oklahoma State Board of Medical Examiners reports 9 physicians licensed to practice medicine by reciprocity from January 16 through May 29. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Howard University College of Medicine.....	(1926)		Dist. Colum.
Tulane University of Louisiana School of Medicine.....	(1935)		Mississippi
Tufts College Medical School.....	(1935)		Mass.
St. Louis University School of Medicine.....	(1937)		Missouri
Washington University School of Medicine.....	(1935)		Missouri
Ohio State University College of Medicine.....	(1939)		Ohio
Western Reserve University School of Medicine.....	(1936)		Ohio
University of Texas School of Medicine.....	(1918)		Texas
University of Wisconsin Medical School.....	(1938)		Wyoming

Kansas June Report

The Kansas State Board of Medical Registration and Examination reports the written examination for medical licensure held at Kansas City, June 17-18, 1941. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Seventy-five candidates were examined, all of whom passed. Ten physicians were licensed to practice medicine by reciprocity and 1 physician so licensed on endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Northwestern University Medical School.....	(1940)	83.7,	
(1941) 83.1, 86.2			
University of Kansas School of Medicine.....	(1941)	79.6,	
79.7, 80.4, 80.7, 80.8, 81.7, 81.9, 81.9, 82.1, 82.2, 82.5,			
82.5, 82.7, 82.9, 83, 83, 83.2, 83.2, 83.2, 83.3, 83.3,

MEDICOLEGAL ABSTRACTS

Autopsy: Liability of Coroner for Ordering Unauthorized Autopsy.—Apparently in the course of his employment Crenshaw collapsed and was taken to the nearby office of a cult practitioner who pronounced him dead and notified the defendant, the county coroner. On the direction of the coroner an undertaker then removed the body to the county hospital. Without ordering an inquest, without making any investigation whatever other than having a telephone conversation with the cult practitioner referred to, in which the coroner was informed that Crenshaw had "reportedly fallen over dead while working," and without himself examining the body, the coroner ordered an autopsy to be performed by the department of pathology of a local medical school. The autopsy was performed without the consent of Crenshaw's widow, who did not learn of it until some time after burial. Subsequently she sued the coroner. The jury returned a verdict for \$5,000 for actual damages and for \$5,000 for punitive damages. The trial court ordered a remittitur of the whole amount of the punitive damages awarded and entered judgment for the total amount awarded for actual damages. The coroner then appealed to the St. Louis court of appeals, Missouri.

The coroner in Missouri, said the court of appeals, is a constitutional officer whose powers and duties with respect to the holding of inquests and autopsies are more or less specifically defined and limited by statute. In the opinion of the court, the decision of the Kansas City court of appeals in *Patrick v. Employers Mutual Liability Insurance Co.*, 233 Mo. App. 251,

118 S. W. (2d) 116 (J. A. M. A. 112:2466 [June 10] 1939), in which the Missouri statutes relating to coroners were construed, was determinative on the issues presented in the present case. In the Patrick case, said the court of appeals, it was held squarely that a coroner is invested by law with no authority to order an autopsy performed except in connection with, and as an incident to, an inquest to be held before a jury on the body of a person supposed to have come to his death by violence or casualty. In the Patrick case the court held that the purpose of an inquest was to inquire, on a view of the body, how and by whom such person came to his death; that, while the coroner acts judicially and has a discretion with respect to determining whether an inquest shall be held, neither the inquest itself nor the calling and holding of an autopsy in connection with it is a proceeding judicial in character so as to relieve the coroner from civil liability for his acts in relation to it; that it was never intended that the coroner should have the right to order an autopsy performed in any case in which, in his mere judgment, an autopsy might be deemed proper for any such reason as the advancement of science or the like, and that while it might or might not be thought desirable that the coroner should have the power to hold an autopsy to determine whether an inquest should be held the law gives him no such authority, so that in the case of a person who is merely supposed to have come to his death by violence or casualty an autopsy performed except in connection with an inquest is unlawful and illegal, regardless of what might be the coroner's good faith in the exercise of a mistaken authority in the matter. Of course, continued the St. Louis court, if the widow, as the person entitled to the right of sepulture, had given her consent to the autopsy, there would have been no liability on the coroner's part (in the absence of a performance of the autopsy in an improper manner), even though no inquest was held or basis afforded for the defendant himself to have declared the cause of death on a mere coroner's view of the body. However, neither the widow nor any one for her gave such consent, and consequently the autopsy must be held to have been unlawful and illegally performed.

The coroner contended that he was justified in ordering an autopsy to enable him to sign a death certificate. The answer to this, said the court, is the fact that, under the statute having to do with the coroner's duties with respect to the registration of deaths, he is authorized to execute a certificate of death only if the case is referred to him by the local registrar of vital statistics because of the absence of an attending physician and because the circumstances of the death render it probable that the death was caused by unlawful or suspicious means. In this case, not only was the deceased receiving treatment from a physician for high blood pressure up to the very time of his death but in addition the case was concededly not referred to the defendant by the registrar for investigation and certification. Neither was the defendant requested by the relatives or friends of the deceased to hold a view or inquest on the body for the purpose of issuing a certificate of the cause of death. In the opinion of the court, the autopsy performed on the body was not to be justified on any such ground.

The coroner next contended that the trial court erred in refusing to permit the physician who performed the autopsy to answer a question put to him on cross examination as to whether the cause of death could have been ascertained without an autopsy on the ground that the question at issue was not whether the cause of death could have been ascertained without an autopsy but whether the defendant had in any event possessed the legal right to direct the performance of the autopsy. However effective, said the court of appeals, an autopsy might have been as a means of revealing the true cause of death, such a consideration would not have excused its performance without legal authority therefor, and, in the absence of such authority, the matter of its desirability was irrelevant to the case unless, perhaps, on the question of the coroner's good faith.

The court of appeals believed an award for actual damages for the unlawful performance of an autopsy was proper even though the only damages sustained by the widow were for

mental anguish. While ordinarily damages for mental anguish are not recoverable unless connected with some physical injury, the trend of modern authority is not to apply such a restriction in the case of interference with rights involving dead bodies, where mental anguish to the surviving relatives is not only the natural and probable consequence of the character of the wrong committed but indeed is frequently the only injurious consequence to follow. The court believed, however, that the amount awarded for actual damages was excessive under the circumstances here present. The autopsy in this case was performed in a proper and scientific manner. There was no mutilation of the body visible to the eye. While the widow undoubtedly suffered mental anguish in more or less degree from the mere knowledge that even a proper autopsy had been performed, a state of grief on her part was none the less a natural consequence of the death of her husband in and of itself, and there was nothing to show that the reaction of which she complained was materially different from that which would have followed in any event if there had been no autopsy performed on the body. The court then adverted to the amount awarded for actual damages in the Patrick case—\$1,500—and felt that that sum furnished an accurate guide beyond which the limits of reasonable compensation for actual damages should not be permitted to extend in the absence of special and unusual circumstances. Accordingly the court, in effect, ordered a judgment for \$1,500 in favor of the widow.—*Crenshaw v. O'Connell*, 150 S. W. (2d) 489 (Mo., 1941).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1931 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Carcinoma of Uterus.—According to Newcomer, fistulas are seldom due to faulty methods of irradiation but to the extension of the disease. Constriction of the ureters, ureteral dilatation and hydronephrosis are also generally due to extension. A dull, nagging pain in the hips, groin or radiating down the thigh or leg may be caused by ureteral obstruction. Cystoscopy and visualization of the ureters are indicated in such cases. Similar symptoms are caused by extension of the disease to the lumbar and sacral nerves and to the uterosacral ligaments. Masses may form on the side walls of the pelvis by extension through the parametrium and broad ligaments, causing excruciating pain. Pressure on the veins of the lower extremities may result in

edema of the lower limbs and external genitalia. Invasion of the rectum may result in stenosis, ulceration, intestinal obstruction and fistulas. If low abdominal pain follows radium application, patency of the cervical canal must be established. Cancerous tissue may be growing upward along the ureters behind the peritoneum with consequent involvement of the abdominal organs and the peritoneum. The disease rarely spreads through the abdominal and thoracic nodes to the supraclavicular regions. Metastasis to the bones does not occur as often in uterine cancer as in other forms of cancer. Roentgen therapy should precede radium therapy. It reduces infection and the size of the tumor, makes the application of radium safer, renders possible the giving of a heavier dose of radium and distributes it more evenly throughout the tumor. It makes unnecessary the giving of radium in divided doses, except in an extremely large uterus. Radium should be given in both the uterine and the cervical canals in doses short of tolerance by the surrounding tissues. As large a dose of radium as can be safely tolerated should be applied to the vault of the vagina by means of the bomb, colpostat or interstitial irradiation in selected cases. Roentgen therapy, by means of at least 300 kilovolts, should be evenly distributed throughout the true pelvis. The treatment is repeated in six weeks. The addition of two lateral fields and another field over the lumbar vertebrae would minimize extensions to the side walls of the pelvis and to the lumbar area, which are especially subject to extensions. The author's method is to cauterize the area from which a biopsy specimen has been taken. Roentgen treatment is then given every other day to two pelvic ports, anterior and posterior, each 20 cm. square. An average size patient receives 1,300 roentgens over each port in fourteen days. Within four to seven days radium is applied. Usually 100 mg. is distributed in 5 mg. needles. The radium usually remains in place for thirty-six hours. Three or four days later a vaginal bomb containing 100 mg. of radium is placed in the vaginal canal against the cervix for from twenty-four to thirty-six hours.

Benign Uterine Bleeding and Fibromyoma.—In Corscaden's experience bleeding was controlled in 98.1 per cent of the 733 cases of uterine bleeding and myoma treated with radium and roentgen irradiation. Thirty (6.1 per cent) of 493 patients treated by radium and 18 (7.6 per cent) of 240 treated by roentgen irradiation required supplementary irradiation. Fourteen (1.9 per cent) of the 733 patients failed to have the bleeding controlled. Five of these received inadequate doses of radium or roentgen rays, 4 were operated on before sufficient time had elapsed for the irradiation to complete its effect and 2 had pedunculated submucous myoma. Three failures were unexplained. Dysmenorrhea disappears when menstruation ceases. Following substerilizing doses this symptom reappears in 66 per cent of the patients in whom menstruation returns. Pain other than dysmenorrhea and urinary symptoms have been relieved in less than 50 per cent. Uterine tumor is satisfactorily reduced in 94 per cent of patients if it is no larger than a pregnancy of five months. When larger than a pregnancy of six months, it has been satisfactorily reduced in only 40 per cent. Following a substerilizing dose of radiation, in only 2 of 15 fibromyomas was the tumor satisfactorily reduced while menstruation still continued. Two patients had symptoms and signs of tumor degeneration following roentgen therapy. In no instance has roentgen therapy caused a pelvic inflammation to flare up. Four patients treated with radium contracted surgical infection following dilation and curettage and the insertion of radium into the uterus. No instance of carcinoma of the uterus has been revealed within two years after radium and roentgen therapy for benign bleeding or myoma. Two cystadenomas of the ovary were discovered four and five years, respectively, after irradiation. The 733 cases were a carefully selected group and represented about 30 per cent of the total number of such cases encountered. The others were curable by conservative methods or presented conditions which contraindicated radium or roentgen therapy. Of the contraindications only the submucous myoma is important as a cause of failure to control bleeding, and carcinoma of the uterus and a neoplasm of the ovary a cause of disaster from neglect.

Gonococcal Vulvovaginitis.—Cohn and his associates made a twenty-eight week follow-up study on 234 cases of gonococcal vulvovaginitis. The superiority of cultures over smears for diagnosis and for determining cure was evident. As the length of observation increases and the disease progresses, or if treatment is instituted, the accuracy of diagnosis by the smear method decreases. Toward the end of the twenty-eight weeks of observation there are few instances of positive diagnosis by either smear or culture. At this time, because some children probably have been reinfected, there is a greater degree of correspondence between smear and culture. Of a total of 1,070 examinations 98.9 per cent were positive by culture and 67.1 per cent by smear. It was found that more than 50 per cent of untreated patients undergo spontaneous cure within thirteen weeks. The carrier state develops in about one fifth of these patients, in whom occasional positive cultures occur in the absence of clinical signs even after twenty-eight weeks of observation. However, all patients ultimately become negative. Sulfanilamide therapy resulted in cure in two thirds of the hospitalized patients within two weeks of treatment. Sulfapyridine was followed promptly by negative cultures in all cases, with recurrence in less than 10 per cent. Estrogen brought about early clinical improvement, but the course of the disease was little different from that in the untreated controls. Rectal cultures were positive in 45 per cent of the patients. In none was there characteristic evidence of gonococcal proctitis clinically.

Transmissibility of Syphilis.—In determining the transmissibility of syphilis, Pariser injected vaginal secretions from 30 untreated syphilitic women under the dorsal skin of mice. The vaginal secretions from 7 women produced syphilis in animals. Five of these 7 women had local cervical lesions. The clinical manifestations of the disease in these instances varied from about one week to six and one-half years. The sixth "positive" result was obtained from the menstrual blood of a secondary syphilitic woman with no local cervicovaginal lesions, and the seventh was produced from an early secondary syphilitic pregnant woman whose cervix was edematous, bluish and boggy, but who presented no visible open lesions. Initial darkfield examination revealed organisms in small numbers closely conforming to the universally accepted morphology of *Spirochaeta pallida* in 4 cases and organisms which were slightly thicker than average but which by subsequent animal inoculation were proved to be *Spirochaeta pallida* in 2 instances; the result was negative in the seventh case. In the absence of lesions the darkfield examination of 50 per cent of the women revealed spirochetes easily distinguished from *Spirochaeta pallida* unless wide latitude is permitted in the interpretation of the spirochetal form of the organism of syphilis. The case material consisted of 76 per cent early (within the first four years of the disease) syphilis and 24 per cent late syphilis. The conclusions from the study that the syphilitic woman discharges spirochetes into the vagina only in the presence of local lesions or through her menstrual blood during the early stages are not to refute the point of view that syphilis may be acquired without the production of a lesion or that the woman may temporarily before or after acquiring the disease harbor the spiro-

chetes on the presumably intact cervix. The conclusions do postulate, however, that, once infection has been acquired, the woman whose biologic reaction is thereby considerably altered to the organism discharges *Spirochaeta pallida* into the vagina only in the presence of lesions which may occur early or chronologically late when the immunity balance shifts toward the development of infectious, relapsing, even though at times inconspicuous and transient lesions. Among the 23 patients the infectiousness of whose vaginal secretions could not be demonstrated there were 5 (4 early and 1 late) from whom two or three vaginal washings were collected on different days to detect any possible changes in the pathogenicity of the flora over one or two weeks. The results were "negative." Their vaginal secretions varied from mucoid to purulent. In 2 instances primary inoculation of vaginal secretions into mice killed the animals within a week.

BCG Vaccination.—Hopkins states that more than 20,000 Montreal infants were given BCG vaccine on the advice of physicians and with the consent of parents. His study is limited to 793 of these children who were exposed to contact with a patient having positive sputum and to approximately 1,200 control children in similar contact not given the vaccine. The children of both groups were drawn from the lower middle and poorer sections of the community. Of 30 deaths from causes other than tuberculosis among the vaccinated children, 4 were confirmed at necropsy and 11 by clinical and laboratory examinations. There were 37 deaths from nontuberculous causes among the control group; 2 of these were confirmed at necropsy and 15 by hospital examination. There were 8 deaths from tuberculosis among the vaccinated group, 3 confirmed at necropsy, 3 by hospital examination and 1 by a specialist in tuberculosis. The remaining child who died was diagnosed clinically as having pulmonary and meningeal tuberculosis, and both parents had active pulmonary tuberculosis. Of the 23 tuberculosis deaths among the control group, 1 was confirmed at necropsy, 10 by hospital examination and 3 by specialists. As to tuberculosis morbidity, there were 37 active and latent morbid cases in the vaccinated group; 32 diagnoses were confirmed by roentgen or fluoroscopic examination and 32 by hospital observation. Among the control group there were 81 active or latent instances of tuberculosis; 71 were confirmed by roentgen or fluoroscopic examination and 77 by hospital observation. With but two exceptions (at the age of 4 and 5) the differences in the general mortality by age of both groups are in favor of the vaccinated children. Even the combined rate for the age groups from 0 to 4 years of age of controls differs from the vaccinated rate of 86 by only 1.8 times its standard error. The morbidity figures favor the vaccinated children. Analysis shows that the oral administration of BCG vaccine at birth substantially reduced the incidence of tuberculosis during the third, fourth and fifth

years of life and that, had larger numbers been available for comparison, there probably would have been significant reductions in the first two years of life. As the vaccinated children were exposed to a slightly higher accumulated duration of contact and were of a lower average age at the beginning of contact, it seems reasonable to ascribe the favorable differences in their "pathologic infection" to the effects of vaccination. The similarity of the vaccinated and control groups in respect to nontuberculosis mortality is not indicative of any pronounced paraspecific immunity resulting from BCG, as has been suggested by some investigators. Acceptable information regarding the duration of the effectiveness of vaccination may be secured only by continued observation of the children now in the lower age groups.

Pulmonary Tuberculosis in Medical Students and Nurses.—Hahn and his associates report the results of tuberculosis case finding (by the intracutaneous tuberculin test and roentgenogram of the chest) among medical and nurse students at Cornell University Medical College and the New York Hospital. The percentage of positive reactors among six first year classes of medical students varied from 75 to 89. Collectively, of the 315 tested 259, or 82.2 per cent, were positive and 56, or 17.7 per cent, were negative. Of three fourth year classes totaling 147 students, 135, or 91.8 per cent, were positive and 12, or 8.1 per cent, were negative. The percentage of positive reactors in the fourth year classes tested was thus 9.6 higher than in the first year classes. Of the total of 278 student nurses of the classes of 1935 to 1941, inclusive, tested in their first year 216, or 77.6 per cent, were positive and 62, or 22.3 per cent, were negative. Of the classes of 1934 and 1936, totaling 69 nurses, examined during their second year 57, or 82.6 per cent, were positive and 12, or 17.4 per cent, were negative. The classes of 1933, 1935, 1936, 1937 and 1938 were examined at the end of their third year, and of 130 graduating nurses tested 119, or 91.5 per cent, were positive and 11, or 8.5 per cent, were negative. The student nurses thus showed an increase of positive reactors from 77.6 per cent the first year to 91.5 per cent at graduation. The percentage of negative reactors shortly before graduation of both medical and nursing student groups varied in different years from 0 to 14.3. The average for the nursing students (of the classes of 1933 to 1939 inclusive) has been 6 per cent negative on graduation and for the medical students 8.7 per cent. A total of 442 medical students had at least one roentgen examination; 71, or 16.1 per cent, had calcified deposits in the tracheobronchial lymph nodes, in the pulmonary parenchyma or in both, and 5 had shadows characteristic of chronic pulmonary tuberculosis in their initial roentgenograms. The lesions were all minimal in extent. Only 2 of the 5 were found in the first academic year. Four other students, who had negative initial roentgenograms, had characteristic shadows of chronic pulmonary tuberculosis in subsequent years. Three were minimal and 1 was moderately advanced. Of these 9 students, 2 per cent of the total, 4 had lesions which were obviously progressive and they were referred to sanatoriums. The other 5 were allowed to complete their course. Of these, subsequent information is available on 2; 1 has never had any symptoms or physical signs attributable to his lesion, which has remained unchanged in serial roentgenograms for four years and the disease of 1 has progressed since his graduation. Roentgenograms of the chest of 269 nurses were obtained and 52, or 19.3 per cent, had calcified nodules and 14, or 5.2 per cent, had doubtful apical shadows of not more than a few millimeters. In none of these did definite pulmonary infiltrations develop during the period of observation. Three nurses were found to have definite pulmonary lesions of the so-called adult type. They were all in the minimal stage when discovered; 2 of them were observed in the initial roentgenogram; thus the disease developed in only 1 of the 269 student nurses during their three years of training. The rates for the nurses and the medical students are considerably below those reported from similar institutions. The tuberculosis rate among the medical students, though slightly higher than that among the student nurses, is not significantly higher than the expected rate for their age group (average 22 years on admission).

Postoperative Gangrene of Skin.—Three cases of progressive postoperative gangrene of the skin reported by Dodd and his co-workers were the first to be seen in an active surgical experience of thirty years. The gangrene of 1 occurred after a suprapubic prostatectomy. Stewart-Wallace collected 37 cases in the period from 1908 to 1935; since then about 40 new cases have been reported, making a total of 87. In 71 cases gangrene developed after abdominal and thoracic visceral operations, and in 16 it followed minor parietal lesions. All of the lesions, with two exceptions (herniotomy and sympathectomy), were primarily due to mixed or single infections. There was a striking

predominance of male over female patients among the visceral group, the proportion being 53 to 17. The parietal lesions were distributed equally. The authors suggest that the male predominance is probably due to the fact that the skin of the male trunk is thicker, coarser and more hairy than that of the female. Thus, staphylococci are inevitably in the hair follicles and virulent streptococci can be introduced into the skin with a needle. Most of the patients (69 of 86) were more than 35 years of age, indicating that progressive postoperative gangrene of the skin is associated with declining vitality. General debility may therefore be a significant etiologic factor. In the 61 in which these data were available the gangrene was generally present within three weeks after operation. All treatment, except with the cautery, is useless. Of 22 fatalities the cautery was used in 8, while of 65 recoveries the wound was cauterized in 52. Two other methods of treatment have emerged; the use of maggots and excision by scalpel. Coakley and Klein succeeded in clearing up with maggots a condition which had persisted in spite of electrosurgical excision. Holman tried this therapy in 3 cases; in 1 the maggots would not stay in the wound and the patient died, and the 2 other patients recovered. Willard had success with a case of gangrene following appendectomy in which the entire lower abdominal wall was involved. He excised the area, the sloughs and the spreading edge in the skin with a scalpel, afterward dressing it daily with a watery suspension of zinc peroxide. Recovery is possible even after the gangrene has existed six months. Thirteen of the 22 patients died within three to nine months after the onset of the disease. Nineteen of the deaths occurred among the 69 patients who were 35 or more years of age. The death rate for visceral lesions was 24.3 per cent, as compared to 31.2 per cent for parietal conditions.

Metastasis from Carcinoma of Breast.—Saphir and Parker found the adrenals, ovaries and spleen to be involved in a surprisingly large percentage of the 43 necropsies on patients with carcinoma of the breast. The most common locations were the lungs (28 instances) and the liver (24 instances), while the next most common locations were the adrenals in 19 instances, the spleen in 10 and the ovaries in 7. These figures when compared with those of older publications are exceptionally high. No metastases were found in 3 instances. It is definitely not the type of carcinoma which is responsible for the shorter or longer survival period of the patient or for the appearance, spread and number of metastases. However, it was found, especially with ductal carcinomas and adenocarcinomas, that whenever the continuity of the lining cells of the glandular structures was interrupted or (as in ductal carcinomas) the integrity of islands of tumor cells was disturbed and individual, isolated tumor cells began to invade the surrounding mammary tissue, this phenomenon constituted the most definite sign of a high degree of malignant change. Isolated tumor cells exhibiting severe anaplasia, separated from primary basic structures of the individual carcinoma and singly or in small groups invading neighboring regions, must be considered the most important factor. Most of the tumors which produced metastases in the spleen, ovaries and adrenals showed an infiltration of isolated carcinoma cells outside the primary tumor. This was especially true for the mucinous carcinoma of the signet ring cell variety. The occasional small and clinically unnoticed carcinoma may give rise to widespread metastases. There were 4 such cases in their series. Such instances emphasize the importance of carefully palpating the breasts during general examination. There was no apparent difference in the survival of patients given postoperative radiation and of those not receiving such therapy.

Renal Blood Flow and Sympathectomy in Hypertension.—Corcoran and Page record observations on renal blood flow and hemodynamics in 2 patients with essential hypertension treated by Smithwick's method of abdominal sympathectomy. The clinical result of the operation in the first patient seems satisfactory, and, although sufficient time has not elapsed for the second patient to justify a prognosis, it seems likely that the result will be nearly as good. The second patient's maximal blood pressure in the recumbent position is no higher, and in the erect posture it is a great deal lower than it was before the operation. There is no evidence, however, of increased renal blood flow. On the contrary, it has decreased definitely in the

first patient and slightly in the second. The decreased renal blood flow in the former is accompanied with an increase of the filtration fraction, probably the result of increased efferent arteriolar constriction. The observations are in accord with experimental data and with those on the effect of renal denervation and sympathectomy in man. It is suggested that the decrease of arterial pressure in man which follows sympathectomy is an expression of denervation of the reactive visceral splanchnic innervation with resultant partial failure of venous return, most evident in the erect position. The decrease of venous return limits cardiac output and thus tends to decrease arterial pressure. The decrease of arterial pressure is in itself an adequate explanation of the clinical improvement which may follow such an operation, since it may prevent further spread of arteriolar lesions. Renal vasoconstriction in cases of hypertension is probably humoral rather than neurogenic in origin. Decreased arterial pressure occurring as a result of sympathectomy may arrest the progress of renal arteriosclerosis in a hypertensive patient. Since these arteriolar lesions may contribute to the release of renin and the activity of the renal vasopressor system, sympathectomy may interrupt for a time the progress of the disease.

Activity After Operation.—Leithauser and Bergo have performed 383 appendectomies since January 1938. There were 13 cases of ruptured appendix and spreading or generalized peritonitis. The average period of confinement to bed after operation for the other 370 patients was one and a half days and the average hospitalization two and three-tenths days. Fifteen patients had minor wound infections. These patients were not confined to bed for treatment but came to the office for dressings. There were no other complications. During the first twenty-four hours after operation the patients were given 2 ounces (60 cc.) of water every two hours and morphine as required to relieve pain. Enemas and cathartics were not given, but liquid petrolatum was prescribed on the third or fourth day. The patients were turned frequently in bed and were instructed to be active and to take deep breathing exercises at regular intervals. On the first postoperative day they were assisted in sitting on the edge of the bed (after assuming the right lateral position) and then in standing beside the bed for deep breathing exercises. While in each position they were instructed to take several deep inhalations and to cough. They were permitted to walk about the room and to sit in a chair for a few moments and then returned to bed. On returning to bed they sat on the edge of the bed and reclined on the right side. The patients left the hospital by automobile and presented themselves at the office on the sixth postoperative day. Most of the patients selected on the basis of their mental attitude and general well-being were permitted to do light work on the eighth day and to undertake heavy manual labor on the fourteenth. The authors were so impressed by the rapid recovery and freedom from complications of these patients that they have since used the method after other major surgical procedures. The results among 66 patients undergoing cholecystectomy, gastrectomy, gastroenterostomy, pelvic operations, splenectomy, thyroidectomy and other operations were also gratifying. Their average period of confinement to bed was two days and postoperative hospitalization nine days. No dehiscence, hernia, pneumonia, thrombophlebitis or other serious complications (except 1 instance of fatal hemorrhage) occurred. The method decreases atrophy from disuse of the sutured layers and may promote healing by improving the circulation in the area of the wound.

- Calcium Requirements of Adults—Outhouse and her associates determined the calcium requirement of 7 adults from 21 to 42 years of age The requirement was computed from data on calcium balances secured at levels of intake almost sufficient

to induce calcium equilibrium and from data concerning the extent to which each subject could utilize milk calcium The requirements, when based on weight, height and surface area, amounted to an average of 107 mg per kilogram These requirements, calculated on a weight basis of 70 Kg, average 752 mg This is 67 per cent greater than the 450 mg requirement suggested by Sherman, whose figure the authors believe is too low because it is predicated on the assumption that adults utilize 100 per cent of their dietary calcium

Calcium Requirement of Adult Man—Twenty-five further calcium balance periods from twelve to thirty-two days each were carried out by Steggerda and Mitchell on 9 adult men The data indicate that Sherman's estimate is too low by reason of the method of derivation, which neglects to consider the close positive correlation between intake and excretion The common procedure of estimating the prevalence of calcium undernutrition in a population by comparing the estimated calcium content of individual or family diets with an average requirement yields extremely dubious data, not only because of individual variability in requirement and utilization of the calcium from different foods, but also because of the great adaptive powers of the human organism It appears that in the presence of an inadequate supply of any nutrient, including calcium, the body can adjust itself to the situation either by a more economical use of the little available or by a lowering of its own requirements, so that eventually it comes into equilibrium with the limited food supply Only during this period of adjustment can the body be considered to be undernourished, since only then is it suffering a loss of nutriment When adaptation is complete, the body replaces from its restricted supply all losses of the nutrient from its body, and, unless some subsidiary ill effects ensue, it may be regarded as adequately nourished

*Favism: Singular Disease Chiefly Affecting Red Blood Cells. A. Luisada, Waltham, Mass.—p. 229.

Weil's Disease.—Ashe and his associates believe that the lower reported incidence of Weil's disease in this country is not due entirely to its less frequent occurrence but that probably because of its protean nature it is not always diagnosed. Most of the American cases occur during June, July, August and September; this concurs with the maximal European incidence, which is in July, August and September. Only 1 nonicteric case has been reported in this country. In Europe, as the disease became better known, the incidence of nonicteric cases rose rapidly, until now analysis shows that not more than 50 per cent have jaundice. As in typhoid, the procedures necessary to diagnose Weil's disease vary and depend on the duration of symptoms. For therapeutic reasons it is most desirable to demonstrate the organism directly in the blood stream in the first week of the disease, when specific therapy (immune serum) is most valuable. As yet American drug houses have not prepared such serums and cannot be expected to do so until city and state laboratories make available the necessary diagnostic procedures and the true incidence of the disease in the United States becomes known. Until immune serums appear on the American market, supportive therapy and convalescent serum or whole blood transfusions should be used when possible. The National Institute of Health at Washington, D. C., is the only public laboratory equipped to do thorough diagnostic and investigative studies on this disease. Weil's disease is primarily an occupational disease now compensable in New York State. The authors report 7 cases of Weil's disease seen within the last year at the Cincinnati General Hospital. All the patients were jaundiced, 5 recovered and 2 died. The postmortem demonstration of organisms in the 2 patients who died confirmed the diagnosis. In the nonfatal cases the diagnosis was proved by specific agglutinations.

Favism.—Luisada suggests that in the future more cases of favism (only 3 have been reported so far) will be recognized in the United States. A large Mediterranean population lives in certain parts of the United States. Fava beans are cultivated extensively in some states (mainly New York, New Jersey, Illinois and California). They are a staple article of diet, being even imported as canned food from Italy. The environment, inhalation, is definitely related to the chief clinical syndromes of favism. Fields of fava beans constitute the usual surroundings in which attacks occur. The pollen is sticky and has no wide dissemination. Attacks caused by ingestion may occur anywhere, but they are more frequent where the custom to consume this vegetable is not occasional. The plant *Vicia faba* (called in Italian and Portuguese "fava," known in English as the "horse bean," "broad bean" or "fava bean") is the cause of the attacks. The first symptoms after inhalation of principles originated in the flowers or plant of the fava bean usually occur from a few minutes to some hours. After ingestion of fava beans the time element is from five to twenty-four hours. In the sudden attacks caused by inhalation the first symptom is dizziness, sometimes reaching the stage of a collapse. More usually malaise, headache, dizziness and nausea appear gradually. Then repeated yawning, vomiting, chill, pallor and pain in the lumbar region are followed by high fever. The more specific symptoms, hemoglobinuria in from five to thirty hours and icterus in a few hours, appear later. Typical attacks last for from two to six days. Death occurs almost only in children and this during the first two days, seldom on the third day. According to Fermi, the mortality for children is 8 per cent. Of the three theories (parasitic, toxic and allergic) advanced for favism the allergic theory is the most commonly advocated and most logical. Luisada confirmed the allergic mechanisms by pointing out the short duration of the incubation period, the innocuousness of the substance for most individuals and the extremely small doses which may provoke an attack. The

allergic theory has since been suggested by many other investigators. Sensitization can occur in persons of any age. Desensitization occurs usually for a short time during and after attacks. Further studies are necessary for the complete explanation of hemoglobinuria. Treatment of the hemolytic attack is important, since it often endangers life and always causes severe anemia. Some of the therapeutic agents used with good results have been normal horse serum, horse serum and mother's blood, mother's blood and intramuscular or intravenous injection of magnesium thiosulfate, epinephrine intramuscularly and calcium gluconate intravenously. Iron may be given, but liver therapy is not indicated. In the absence of specific treatment the most effective preventive measure is the avoidance of contact with fava proteins, especially from April to August.

Traumatic Heart Block.—Coffen and his associates report the case of a boy who at 3 years of age (in 1922) sustained a severe fall and from then on his mother noticed that his pulse was slow. At examination in 1929 the boy presented a complete auriculoventricular block. He has been seen frequently since 1929 and, while the heart block persists, the boy, now 21, has developed normally, is physically active and has no symptoms of cardiac strain or Stokes-Adams syndrome. In the last ten years he has been examined at least once a year. There have been no changes in the electrocardiogram during this time. The case is unique because (1) it is the only case the authors are able to find in which auriculoventricular block occurred from injury in childhood, (2) there are only 5 other cases in which auriculoventricular block resulted from nonpenetrating injury, (3) it has persisted for eighteen years in their patient and (4) there has been no evidence of heart failure or Stokes-Adams syndrome.

Familial Darier's Disease.—Hitch and his collaborators report the occurrence of Darier's disease in 14 members of one family. Only 6 of the affected members are still alive. The authors were told that the disease in the deceased relatives was identical in regard both to history and to appearance. The family is intelligent and observant and has lived within a restricted region for several generations, so that the information is considered reliable. This family has yielded the largest number of cases of the disease on record. Complete data have been obtained on six generations. There are in all 52 blood kin on whom the authors have sufficient data to be reasonably sure of the presence or absence of this affliction. Of 27 males 4, and of 25 females 10 showed the disease. The average age of the affected dead individuals was 59 as against 47 years for those free of the condition. An examination of the family chart and of those previously reported will show that in familial cases the aberration is transmitted through and to both sexes. The successive appearance of the disease in each generation and its absence in the offspring of normal members rule out the possibility that a simple recessive characteristic is being dealt with. All evidence to date indicates that in the familial cases the abnormality is caused by a single dominant non-sex linked gene. For the isolated case of Darier's disease they believe that the genetic theory which probably best explains this situation is that of "irregular dominance." According to this concept the expression of a certain gene may be modified by another gene or group of genes. The modifiers may enhance or suppress the expression of the character. A gene which is usually dominant may be present in an individual and yet not be phenotypically visible because it has been suppressed by a modifier. It is most probable that one of these situations exists in Darier's disease. In the sporadic patient it must be assumed that the combination is present in toto but is not accessible to examination in other members of his family. The treatment of this condition is uniformly unsatisfactory. Since approximately 50 per cent of the offspring of diseased members will be affected and transmit the disease in similar ratio, avoidance of children by the intelligent patient and sterilization of the unintelligent or uncooperative patient appear justified.

Osteomyelitis and Staphylococcal Septicemia.—Results obtained at Duke Hospital in the treatment of acute osteomyelitis with staphylococcal septicemia suggest that with the exception of sulfathiazole the sulfonamides are contraindicated. The local use of sulfathiazole appears to be beneficial. There were 143 instances of staphylococcal (86 with osteomyelitis) among 827 proved cases of staphylococcal disease. The present study is concerned primarily with osteomyelitis. Of the 143 instances of staphylococcal septicemia 79 patients died, giving a total mortality rate of 54.5 per cent. Of the 67 patients not treated with staphylococcus antitoxin 51 died and 16 survived, a mortality

rate of 76 per cent; whereas of the 50 patients treated with staphylococcus antitoxin without chemotherapy 16 died and 34 survived, a mortality rate of 32 per cent. Chemotherapy other than sulfathiazole was combined with the antitoxin in the treatment of 16 patients; 5 survived and 11 died. Sulfathiazole was combined with antitoxin in the treatment of 10 patients; 9 survived and 1 died. Of the 86 patients with proved staphylococcal septicemia with osteomyelitis 33 did not receive staphylococcus antitoxin; 11 of these survived and 22 died, a mortality rate of 66.6 per cent; 1 of the 11 who survived received sulfathiazole. Thirty-five patients were treated with antitoxin without chemotherapy; of these 27 survived and 8 died, a mortality rate of 22.5 per cent. There were 9 patients with osteomyelitis and staphylococcal septicemia who were treated with antitoxin and sulfathiazole; 8 survived and 1 died. Of 9 patients treated with antitoxin and chemotherapy other than sulfathiazole, 6 died and 3 survived. In hemolytic staphylococcus infections the ratio of mature to immature polymorphonuclear leukocytes in the circulating blood can be used to estimate the degree of toxemia and to determine the need for antitoxin. Highly purified antitoxin serum can be administered intravenously if the necessary precautions to determine the patient's sensitivity have been taken. Sulfanilamide and sulfapyridine are contraindicated.

Abdominal Arterial Apoplexy.—Bunch and Madden report the seventeenth case of abdominal apoplexy. The diagnosis was made from the history of marked arteriosclerosis in an elderly (62 years of age) Negro having abdominal crises with shock, followed by abdominal swelling, and from the finding of intraperitoneal blood by paracentesis, with a hemoglobin content higher than that of the capillary blood. Treatment immediately following the abdominal attack is that of internal hemorrhage. After reaction from shock has taken place, enough blood should be given by repeated transfusions to raise the blood pressure and the hemoglobin index to within operable limits. At laparotomy, if the patient is a woman of childbearing age, the pelvis should be examined for tubal abortion or rupture. In men without aneurysm or malignant neoplasms, spontaneous rupture of the spleen, the liver or the pancreas is the most common cause of nontraumatic intra-abdominal bleeding. In spontaneous arterial rupture the bleeding point should be found and hemorrhage controlled by ligature or suture, and if neither is possible by gauze pack. Every 1 of the 16 cases of spontaneous rupture of a visceral artery with massive hemoperitoneum reported in the literature has had arteriosclerosis as a base.

Treatment of Penetrating Wounds of Brain.—Pitcher points out that most penetrating wounds of the brain in civilian and in military life are cared for by the general surgeon, who should remember that every compound fracture of the skull is potentially a penetrating wound of the brain. Treatment should not be attempted without adequate neurosurgical facilities. First aid should consist of superficial cleansing and shaving, control of hemorrhage and treatment of shock. Most important is rapid transportation to a point at which operation can be performed. During transportation the head should be moderately elevated (unless shock is present). Evacuation of the wounded by airplane, as it is now practiced by the German army, has met with considerable success. However, in open head wounds the low atmospheric pressure of high altitudes may increase cerebral herniation. In the author's experiments, immediate removal of foreign bodies in twelve hours resulted in 75 per cent recovery and their removal after twenty-four hours resulted in 75 per cent fatality. The complete removal of foreign bodies is not always feasible or wise. Great depth of penetration or lodg-

ment in the opposite hemisphere from the point of entrance renders removal difficult, and the damage caused thereby is too great to justify the procedure. The bullet itself is not often a source of pathogenic bacteria. Contamination is much more likely to arise from fragments of skin, hair, clothing, dirt and other material that has been driven in. If cleansing is complete and damaged tissue thoroughly removed, and if the wound is closed within a few hours the danger of a retained projectile is minimized. The brain tolerates foreign bodies well. The author cites 2 cases which support the rational advice of Cushing that foreign bodies should be removed only if their removal does not increase the existing cerebral damage. The location and depth of the wound influence not only the degree of residual disability, if the patient recovers, but his chances of recovery. In addition to the high mortality resulting from laceration of large arteries or the great venous sinuses, penetration of the ventricular system (particularly if early operation is not possible) and injury of the brain stem, midbrain or hypothalamic region are of grave prognostic importance; they usually terminate fatally. These structures may be unexpectedly involved by seeming distant wounds. For patients not seen until frank infection is present (or in the borderline period from twelve to twenty-four hours when infection may develop) immediate open drainage offers the only hope of avoiding a fatal outcome. The bony opening should be from 3 to 4 cm. in diameter, the dura left open and a soft tube or even small gauze packing inserted to the bottom of the cavity. The once dreaded cerebral fungus will develop. However, the danger from it is in reality small if drainage is adequate and the cerebral infection becomes localized. For the patient seen after healing of such an infection because of convulsions, paralyzes or other disabling symptoms, excision of the cicatricial mass is indicated. The author states that, for traumatic neurosurgery, carefully trained and experienced operative teams and elaborate equipment, though desirable, are not essential. However, two devices, a strong suction apparatus and a high frequency, damped-wave electro-surgical unit, are almost indispensable. Without them adequate débridement and control of hemorrhage are all but impossible. All macerated scalp tissue, free fragments of bone, devitalized brain tissue and accessible foreign material should be removed, but the injury already sustained should not be increased. Gentle irrigation will "float up" all but the largest foreign fragments, and careful suction will cleanse the tract and facilitate complete hemostasis. Temporary gentle packing with moist cotton may be useful. Gauze should never be used on the brain. All wounds free of infection should be closed tightly with fine silk. A drain inserted into the brain is an open invitation to infecting organisms, and it increases the danger of cerebral herniation. If loss of skin has been extensive, it may be possible to close the defect by "relaxation incisions." The exact field of usefulness and the true effectiveness of the sulfonamide drugs in craniocerebral wounds contaminated by bacteria have not yet been finally determined. The Canadian and German armies are using them for prophylaxis and therapy. Extensive studies on the subject are in progress.

Grafting of Adrenal in Addison's Disease.—Katz and Mainzer discovered only 5 instances of successful adrenal grafting in Addison's disease. They add to this list a sixth instance of successful grafting in an indisputable case of Addison's disease. The patient was under their care for nearly three years before operation and for fifteen months after. Just before the operation the amount of extract necessary was 40 cc daily, but still the blood pressure dropped to 70 mm. In this crisis it was decided to graft into the patient the left adrenal gland of a man who had just died from a cerebral tumor. The donor was 52 years of age and belonged to the same blood group. The graft was made into the abdominal musculature on the left side. Soon after operation symptoms of adrenal insufficiency, such as increased somnolence, uncontrollable vomiting, frequent diarrheal stools, collapse of circulation and fall of blood pressure to 60 mm., reached their climax despite daily administration of extract up to 80 cc and that of salt up to 50 Gm. The condition improved within three days of the operation, the dose of extract was reduced and none was given after the seventh day. The patient declared that she felt well. She left the hospital on the sixth postoperative day. During the next two months the blood pressure varied between 115 and 135 mm., the color of the skin, which was yellowish with a clay tinge, became lighter and the freckle-like spots present on the backs of her hands and face were no longer so intensely colored. Any great exertion or excitement always produced slight somnolence and pain in the back. During an attack of influenza, when the blood pressure dropped to 80 mm., from 10 to 20 cc. of adrenal extract was necessary for a few days.

Reactions After Transfusion of Stored Blood.—Jewesbury points out two complications which may develop after transfusion of fresh or stored blood as a result of an incomplete understanding of the technic of blood transfusion. They

are pulmonary edema with cardiac failure due to overloading of the circulation of a patient whose heart is already embarrassed, and renal failure due to transfusion of incompatible blood. The reaction more usually apt to occur after a transfusion is a febrile one. Transfusion reactions are divided into grade 1, a rise of temperature to 100 F., with no other objective features; grade 2, a similar or greater rise of temperature, with a subjective feeling of cold and shivering, and grade 3, fever with a definite rigor. The average incidence of grade 3 reactions in three careful investigations on the use of fresh blood for 700 patients was 7.9 per cent. After transfusion of stored blood the average incidence of grade 3 reactions among more than 5,000 transfusions was 5.6 per cent. The use of 700 bottles of stored blood (average age of the blood was ten and eight-tenths days) from the North-East London depot gave 11.3 per cent grade 1, 4.4 per cent grade 2 and 4.1 per cent grade 3 reactions. In this series the author observed that the average age of the blood causing grade 2 reactions was thirteen and four-tenths days, while that of the blood causing grade 3 reactions was twelve and seven-tenths days. There were 4 instances of urticaria resulting from transfusion of stored blood. Six cases of jaundice seemed to be the result of transfusion of somewhat older blood, since all but one of the bloods used was stored for fourteen or more days. Since even fresh blood contains many aged erythrocytes, rapid destruction of these is to be expected after their transfusion. The degree of destruction increases with the age of the blood. As a routine blood preserved for more than three weeks should not be used, since both in vitro and in vivo hemolysis may result in transient jaundice and possibly be the cause of other reactions. Bushby, Kekwick, Marriott and Whitby have shown that the increase in plasma bilirubin of the recipient is due not to free hemoglobin in the transfused blood but to in vivo hemolysis of transfused cells. It is likely that the febrile reactions after transfusion of old blood are due to products of disruption and degeneration of erythrocytes rather than to the free hemoglobin present in solution. The preservative solutions should be those most likely to prevent the early breakdown of erythrocytes. Hemolysis is impeded by dextrose. In the transfusion of 50 bottles of blood (33 transfusions) preserved for an average of eleven and one-tenth days without dextrose the results were, respectively, 18.2, 15.1 and 12.1 per cent grade 1, 2 and 3 reactions. There were also 1 instance of urticaria and 1 of jaundice. The ready availability of stored blood outweighs any slightly smaller rise of hemoglobin percentage that may occur in the recipient. The disadvantage of stored blood resolves itself about hemolysis, but with modifications of the preservative solution the life of the erythrocytes can be further prolonged. There is now less need to preserve emergency supplies of blood for long periods, as plasma or serum, which can be stored for months, can be given as an emergency measure when whole stored blood is not available.

Glasgow Medical Journal
17:141-172 (May) 1941

- *Glycosuria in Recruits A A T. Peel and Mary W. Peel—p. 141.

Glycosuria in Recruits.—The Peels state that 115 instances of glycosuria have been referred to them by three medical boards during thirteen months. They encountered cases which cast doubt on the wisdom of placing too much reliance on a sugar tolerance curve in differentiating between diabetic and innocent glycosurias. The fact that emotion influences the suprarenals, the thyroid and other endocrine glands indicates that it is also probably capable of producing temporary alterations in the sugar tolerance curve. Diet affects the curve, a factor difficult to assess in recruits. A full medical history and a clinical examination are imperative, and a specimen of blood should be taken forty-five minutes after the test dose of dextrose as well as the routine specimens; without this specimen, a diagnosis of renal glycosuria is not justified and a diagnosis of "lag curve" may be mistaken. Diabetic curves (more than 180 mg. in all specimens or more than 200 mg. in one) were obtained in 43 of the 115 recruits, borderline diabetic curves in 9 and lag curves in 12, and 59 had low renal thresholds (blood sugar below 180 mg. per hundred cubic centimeters). Two of the 59 had diabetic curves, 4 borderline diabetic curves and 4

MacLean's lag curve, and 3 others were excluded from consideration because of insufficient data. Among the 46 remaining recruits with renal glycosuria the blood sugar curve of 30 was normal and 16 had abnormal features, although the maximal level never exceeded 180 mg. per hundred cubic centimeters. Of the 30 having renal glycosuria with a normal blood sugar curve, 14 were admitted because of symptoms suggesting diabetes; 4 denying thirst, polyuria and loss of weight were admitted because of other suggestive symptoms, and 12 had no symptoms suggestive of diabetes, but 2 had chronic nephritis. One had fever and tachycardia, 1 a gross cranial deformity and 1 a history of attacks of colic; 1 was below average weight but of good "physique," the general condition of 1 was "fair" and the general condition of 5 was good. Of the 16 recruits having renal glycosuria with abnormal blood sugar curves, 4 had symptoms suggesting true diabetes, 4 seemed susceptible to infections and 8 patients had no diabetic symptoms, but 5 of them suffered from some other form of ill health: anemia, hypertension and albuminuria, slight cardiac enlargement of doubtful cause or nervousness and tremulousness. Nineteen of the 43 with diabetic curves admitted diabetic symptoms; 9 denied thirst, polyuria and loss of weight but seemed to have a susceptibility to boils or cutaneous infections, 15 denied all diabetic symptoms, including susceptibility to boils, but 5 complained of neurasthenia, duodenal ulcer, chronic otitis media or acute rheumatism and pleurisy. No compunction was felt in rejecting as unfit for service those patients who admitted diabetic symptoms and those who suffered from some other complaint. Only 2 of the 9 recruits with borderline diabetic curves admitted diabetic symptoms. Of these 9, 4 had low renal thresholds. Nine of the 12 with lag curves admitted diabetic symptoms on cross examination. The prevalence of thirst, polyuria or loss of weight among these 12 exceeded that of patients with a diabetic type of curve.

Meningococcal Infection.—Moss states that failure to obtain organisms in blood cultures is of no significance when typical signs and symptoms of meningococcal septicemia are present. Treatment should not be withheld too long. More widespread knowledge of the significance of the typical rash in conjunction with other symptoms will lead to a diagnosis in many cases at the first examination. This is of great importance today, as sulfapyridine is capable of bringing about a speedy cure. This prompt therapeutic response is an additional diagnostic feature. Results with sulfapyridine in meningococcal meningitis have been spectacular, and it was to be expected that they would be even better in the slow forms of septicemia without meningeal localization. A disease that may entail weeks or months of illness and may end in meningitis or even meningococcal endocarditis with or without other complications can scarcely be called benign in spite of a strong tendency to spontaneous cure. For immunologic reasons more cases are likely to be encountered in the later stages of an epidemic. His first case was one of chronic meningococcal septicemia, lasting at least thirty-three days and terminating in meningitis. Progress was uninterrupted except for nausea from the sulfapyridine. The patient was allowed up on the fourteenth day and, at the time of writing, is quite well. The second patient was treated with sulfapyridine for six days, receiving a total of 23 Gm. of the drug. Thirteen days after chemotherapy was instituted examination of a nasopharyngeal swab did not reveal *Neisseria meningitidis*. The onset of subacute and chronic forms of meningococemia is usually, but not invariably, sudden, with malaise, shivering, pains in the limbs, especially the legs, and recurrent headache of varying intensity. This is true also of meningeal signs. Pain in the extremities is not necessarily confined to joints; a joint effusion may or may not be present. With the shivering and rise of temperature there may be a profuse cutaneous reaction and attendant discomfort, yet the patient may feel quite well with the fall of temperature. This comparative well-being has impressed most of those who have seen such patients. The temperature may resemble that of malaria or it may be of the common "septic" type. The rash of meningococemia, once seen, is not likely to be forgotten. Minor variations exist, but in general the same basic pattern is present. The lesions consist of pink or red macules and papules from a pin's head to a threepenny piece in size; a few larger lesions are often present. The smaller ones are roughly circular; the larger ones are often longer than they are broad. The large ones are usually tender. The limbs are usually most affected; but lesions are commonly seen on the back and chest, sometimes the abdomen and more rarely the face. The color may be uniform or the center more vivid. Complete disappearance with pressure is the rule, except when there is a petechia in the center. Isolated petechiae may coexist. Tender papules or nodes may be found on the shins. They may be confused with erythema nodosum or erythema multiforme. The lesions usually fade in a day or so, some completely, or a faint brown stain of some may persist for some days. At intervals, often corresponding with fever, other lesions may appear. Herpes labialis carries as much diagnostic weight as it does in meningitis.

Sulfathiazole for Gonorrhea.—Miescher and Schnetz present conclusions regarding the effect of single and fractionated doses of sulfathiazole in the treatment of gonorrhea. They found that while single massive doses (3 Gm.) yielded cures amounting to 89.5 per cent (thirty-four cures in 38 cases), fractionated doses, distributed over one, two or six days, gave still better results, namely 97.5 per cent (forty-one cures in 42 cases, in which 1 Gm. was administered seven times for one day at intervals of two hours); 98 per cent (fifty-five cures in 56 cases, in which 1 Gm. was administered five times daily for two days), and 97.5 per cent (eighty-one cures in 83 cases, in which 1 Gm. was administered seven, six and five times daily during six days). Experiments undertaken in 35 cases by increasing the single massive dose from 3 Gm. to 5 Gm. not only failed to produce better results but seemed to suggest chemotherapeutic "fastness," though blood and urine analyses did not indicate a decrease of absorption or an increase of excretion. In additional appraisals of the therapeutic value of single and fractionated doses involving uncomplicated gonorrhea, the authors found that a minimal daily dose of 0.5 Gm. given daily for four days achieved the same results as the same total doses (2 Gm.) given at one time (seven cures in 9 cases). No close connection was observed to exist between drug concentration levels in the blood and recovery. However, higher concentration levels more frequently, on the average, accompanied the cure. Laboratory tests for bacterial chemoresistance in cases which did not respond to treatment demonstrated a temporary bacteriostatic effect of the drug in the face of bacterial multiplication observable in the pus. Chemosensitivity was seen to be extremely variable in different strains, fluctuating strongly within concentration limits of 1:1,000,000 and 1:600. The most chemoresistant strain was derived from a patient who recovered. Cultures on ascitic agar likewise showed considerable variation with regard to the antibacterial potency of different serums. Some gonococci were almost serum fast, others showed extraordinary serum sensitivity. According to the authors, the therapeutic effect of sulfathiazole must be sought not only in the combined interplay of high drug concentration levels, bacterial chemosensitivity and the antibacterial properties of the serum but also in other factors, among which the individual degree of immunity seems to be the most important. Massive single doses may constitute the dosage of choice for patients who cannot be relied on to carry out instructions.

Local Sulfathiazole Therapy in Wounds.—Brunner and Schläpfer discuss the therapeutic value of locally applied sulfathiazole as observed in 109 cases of trauma with varying degrees of tissue damage, the majority of which were head wounds (51) and face and limb cuts (18). The drug was used in powdered form (20 cases) and in combination with boric acid (89 cases) in a 20 per cent concentration. This was insufflated on and into the wound. The quantity of the drug used ranged between less than 1 and 7 Gm., according to the nature of the lesion. Wound excision was not practiced; ragged edges were merely trimmed. Immobilization and

serum prophylaxis were regularly employed. No inflammatory reactions, no cellular or tissue damage and no delay in recovery were noted. No difference in results was seen when sulfathiazole was used alone or with boric acid. Microscopic tissue examination after administration disclosed distinct bacteriostatic and bactericidal effects. The growth of hemolytic streptococci, *Bacillus mesentericus* and *Bacillus subtilis* was controlled by the drug. Hemolytic staphylococcus aureus, non-hemolytic streptococci, *Bacterium coli* and enterostreptococci were reduced respectively in virulence to 21, 36, 16.6 and 33 per cent and Fränkel-Welchii bacillus to 13 per cent. The therapeutic value of sulfathiazole used locally lies in the antibacterial effect produced by the combination of high concentrations with slow solubility, which is suited to the latent period preceding bacterial invasion of the tissue. Hence the sooner the drug is applied to the wound the better. The authors regard a 20 per cent strength as too powerful for puncture wounds with narrow openings and recommend injections in aqueous solution or a 2 to 5 per cent administration of sodium sulfathiazole. In multiple lesions 0.5 Gm. per kilogram of body weight is well tolerated locally and systemically.

Sulfathiazole Therapy in Obstetrics and Gynecology.—Winzeler's report covers 200 cases observed during a period of eight months. In order to determine the prophylactic value of sulfathiazole in normal births, the author treated a number of pregnant women and controls with a total dosage of 10 Gm. during five days. In another series of 120 pregnancies (half acting as controls) he increased the total dosage to 11.1 Gm. In both series, judged by fever indications and the number of days intervening between rising after delivery and discharge from the hospital, with urinalyses made after delivery and a week later, no difference in results could be determined. In 40 puerperal cases with labor complications (forceps delivery [15], intrauterine intervention [14], cesarean section [11]) concentrated doses ranging between 17 and 26 Gm. and given in accordance with the same criteria, the action of sulfathiazole was regarded as favorable. In a gynecologic group of about 20, the rarity of septic abortion and the absence of bacillary indications in the blood did not furnish enough data for therapeutic appraisal. Sulfathiazole administered *sub partu* was found in the blood and amniotic fluid of the child, but no regular connection between the sulfathiazole levels of the child and the mother could be established. There was little secretion of the drug in the mother's milk. Numerous blood and urine tests showed no hemopoietic or renal damage. No serious sequels resulted from doses as high as 60 Gm. The author does not consider the use of sulfathiazole indicated in normal delivery. The drug seems to possess considerable therapeutic value in cases of light and mildly severe puerperal infection. Its efficacy in grave cases is limited, since secondary foci have already established themselves. The drug should not be given until signs of infection appear. Sulfathiazole was found to be readily tolerated, of moderate toxicity and well adapted for prolonged use, as in cystitis.

Local Sulfathiazole Therapy in Gynecologic Cases.—

Flagg and Koenig report 14 cases of cervicitis, 9 of which were associated with adnexitis, in which sulfathiazole could be applied locally with sufficient regularity to bring about 9 cures and 5 improvements in leukorrheal and other vaginal discharges, together with relief from pain. Nine additional cases were favorably affected in spite of irregular or incomplete medication. The dosage was put up in special form and inserted into the cervical canal adjacent to the infected glands in quantities and at intervals adjusted to the individual case. Cervicitis was due thrice to childbirth, twice to abortion and four times to gonorrhea; in the other cases the etiologic factor was unknown. Cures were effected even in chronic cases (four years, twelve years). The authors were induced to experiment with local medication by the fact that oral use had often yielded only slight and temporary relief in spite of heavy dosage. They found that the local application not only spared the general system the pharmacologic effects but achieved results in much smaller quantities in cases in which much

larger locally administered quantities had failed. A case is cited in which 0.6 Gm. given locally cured where a total of 40 Gm. given orally had proved unavailing. In 8 of the 9 cases of adnexitis, the disappearance of leukorrhea was accompanied with adnexal amelioration, obviously because the drug exerted its potency on the adnexa by way of utero-ovarian lymphatics. Complications were few. First applications, however, seemed to cause a temporary mechanical irritation quite apart from their antibacterial action.

*Lymphatic Tissues of Rhinopharynx in Hypertrophy of Thymus After Roentgen Irradiation of Thymus. S. Lentini and A. Cirenei.—p. 359.

Hypertrophy of Thymus.—Lentini and Cirenei observed 19 prepuberal children with hypertrophy of the thymus and the thymic syndrome of obesity, genital hypoplasia, retarded puberty and intelligence, and hypertrophy of the lymphatic and adenoid tissue of the nasopharynx. Pharyngoscopic examination and biopsy of the palatine tonsil were made before roentgen irradiations of the thymus, repeated four or five months after the last irradiation. The patients did not have opotherapy or other treatment in the course of the observation. Irradiations were given every other day in doses of from 90 to 100 roentgens for each irradiation, up to a total of four irradiations, this being followed by twenty days of rest and a new course until three had been given. Irradiations were given at a distance of 30 cm. with rays obtained with 150 to 180 kilowatts and 4 milliamperes, through a filter of 0.5 mm. of copper and 0.3 mm. of aluminum. Care was taken to shield the tonsillar region from the irradiating conc. Except for 1 syphilitic child, treatment resulted in marked improvement of the general, physical and mental condition of the patients as manifested by loss of fat, increase in stature, growth of genitalia, initiation of puberty, normal behavior and intelligence. The nasopharyngeal lymphatic tissues regressed proportionally to the general improvement. The authors reported in a previous article that the removal of the thymus in dogs caused regression of nasopharyngeal lymphatic tissues. Clinical observations agree with the animal experiments. The authors point out the advantages of roentgen irradiation of the hypertrophied thymus. The syndrome caused by thymic hypertrophy as well as the hypertrophy of the nasopharyngeal lymphatic and adenoid tissue are controlled by irradiation.

*Roentgen Irradiations of Thymus in Pende's Hyperthymic Syndrome: Technic and Results. G. A. Calabrese.—p. 337.

Roentgen Treatment of Hyperthymism.—Calabrese describes the mental, genital and somatic syndrome caused by hyperfunction of the thymus occurring in childhood. It becomes more evident at puberty. The syndrome consists of arrest of the psychic and somatic development of the person, psychic and somatic infantilism, obesity, retardation of puberty, reversal of sexual characteristics and similar changes. There is a hyperplasia of the lymphatic tissue, especially of the thymus, hypoplasia of the genital organs and cryptorchism. The thymus is enlarged, but the enlargement cannot be recognized roentgenoscopically or by insufflation of air or oxygen into the anterior mediastinum. The diagnosis is made from clinical symptoms and signs of enlargement of the thymus obtained on percussion of the thymus area. The treatment consists of roentgen irradiation of the region of the thymus, given in four series twenty days apart. Each series consists of four exposures of 80 or 100 roentgens given every other day. The author administered this treatment to 377 patients (335 boys and 42 girls) of ages from 4 to 12. Endocrine and physical therapy had failed previously. The roentgen treatment alone, or with temporary administration of glandular preparations, brought about improvement in the general condition of all patients and a complete cure in 90 per cent. By cure the author means disappearance of the abnormal and reestablishment of the normal general, genital, somatic, sexual and mental states. Menstruation appeared in girls of

puberal age or before they reached the age of 20 within two months after treatment was begun, and after two months in girls over 20. The treatment failed in a case associated with hypophysial nanism. Forty-three boys presented cryptorchism, which was unilateral in 3 cases. Five disappeared from control after having had three courses of roentgen irradiations, 29 were cured after three months of treatment and in 4 the testis descended before the first three months of treatment. The latter failed in 3 cases in adults. Results for the entire group were satisfactory, especially with regard to amenorrhea and cryptorchism.

*Liver in Chronic Tuberculous Enteritis: Anatomic and Microscopic Study. F. Parini.—p. 65.

Liver in Chronic Tuberculous Enteritis.—Parini reports a microscopic study of livers from 50 cadavers of patients dying from grave chronic ulcerative tuberculosis and from 50 dying from pulmonary and extrapulmonary tuberculosis without intestinal involvement. Cases of peritonitis, tuberculous lymphadenitis of the upper abdomen and tuberculous lesions of the pancreas or the spleen were excluded. He found fatty degeneration of the parenchyma of the liver of portal origin in all cases of ulcerative intestinal tuberculosis. It was selectively located at the periphery of the lobe in the areas supplied by the portal venules. The lesion occupied about one third of a lobe. In some cases, however, the entire lobe was involved by fatty degeneration with older lesions at the periphery. Fatty degeneration of the liver of portal origin paralleled the acuteness of the intestinal tuberculosis. In all cases of chronic intestinal tuberculosis but 13 peripheral fatty degeneration of the liver coexisted with some other alteration of the structure such as stasis in the hepatic venules in 8 cases, diffuse generalized miliary tuberculosis of the liver without miliary tuberculosis of other organs in 15 and with involvement of other organs in 5, interstitial miliary tuberculosis in 4 and early subacute interstitial hepatitis in 5. In the presence of stasis there are two zones of fatty degeneration, the perilobar caused by tubercle bacilli or their toxins by way of the portal vein, and the central due to stasis. Diffuse miliary tuberculosis of the liver without miliary tuberculosis of other structures is of portal origin and is to be differentiated from miliary tuberculosis of the liver of arterial origin. In the portal type the tubercles are minute, evenly distributed, recently formed and of a necrotic exudative type. The massive passage of tuberculous material from the intestine to the liver through the portal blood with consequent isolated miliary tuberculosis of the liver takes place only when the defense mechanism of the liver abruptly fails shortly before death. Chronic hepatitis of a sclerotic type does not complicate chronic intestinal tuberculosis the course of which is rapid. Death takes place before establishment of chronic disease of the liver.

*Pigmented Secretions of the Breast Simulating Bleeding Breast. C. Stajano.—p. 243.

Pigmented Secretions of the Breast.—Stajano observed 20 cases of pigmented secretion of the breast simulating a bleeding breast and persistence for from six to fifteen years. The secretion increased near or after menstruation in some of the cases and was associated with premenstrual pain in others. Benign macroscopic or microscopic cysts existed in all. Cytologic examination of smears of secretions failed to show either fresh or modified erythrocytes. The secretions were negative for blood and hemoglobin, and positive for melanin. They contained large numbers of phagocytes and a few lymphocytes. They did not contain bacteria. The prognosis is good. Opotherapy is of no effect. The successful treatment consisted in improving the general resistance by administration of calcium, strychnine and arsenic. Involution following surgical castration brought about cessation of the secretion.

Exophthalmic Goiter and Thymus.—Sunder-Plassmann states that he has come to realize through his own studies that some of the contradictions encountered in literature with regard to the role of the thymus in exophthalmic goiter are only apparent and in reality reflect different phases of a single biologic mechanism in the center of which is the thyroid, the thymus and the sympathetic and the parasympathetic with a special neurohormonal cell system. He had observed in thyroids of the newborn cell complexes with light nuclei which in his animal studies he had designated as neurohormonal cells. They are closely connected morphologically as well as functionally with the sympathetic portion of the vegetative nervous system. In dissecting the thyroid and the thymus of the newborn the author frequently observed narrow connections between the two. These connections appear as whitish, delicate formations which the author designated as the white "thymus street" of the thyroid. Serial sections of this structure reveal many large epithelioid cells with light nuclei. These neurohormonal cells represent a unique cell system controlled by the vegetative nervous system and connecting the thyroid and the thymus in a biologic complex mechanism. The thymus undergoes regressive changes, which commence when the thyroid is at the height of activity. The regression is characterized by the presence of a large number of Hassall's corpuscles and by the predominance of the lymphocytic cortex tissue. The medulla and cortex of the thymus seem to play entirely different roles. The medulla forms the epithelioid neurohormonal cells, which are largely dependent on the parasympathetic elements of the vegetative nervous system. The function of this neurohormonal cell system is the absorption of the colloid, thus providing the organism with thyroid secretion. The thymus cortex appears to have the function of fixing such colloid as is secreted too suddenly or in excessive quantities. It seems probable that the thymus serves chiefly the thyroid, with which it has close embryologic relationships. Further evidence of fixation of the thyroid secretion by the lymphocytic cortex of the thymus is offered by the occurrence of atrophy of the thymus after thyroidectomy and the fact that this atrophy can be transformed into hypertrophy, particularly affecting the thymic cortex, if thyroidectomized patients are fed thyroid extracts. The fact that the thymus may atrophy after prolonged activation of the thyroid, as well as in its complete absence, is only an apparent contradiction. In the delicately adjusted biologic mechanism of the neurohormonal thyroid-thymus system, manifestations of irritation, reactive changes and functional impairment may become manifest in the different and not always the same links of the chain and thus cannot be expected in all cases. Reactive changes in the thymus are closely connected with the activity of the thyroid and its effects in the organism. Adrenals and gonads probably play a secondary role in the neurohormonal thyroid-thymus system.

- Vitamin B₂ Content and Tissue Respiration in Brain. H. Leemann and E. Pichler.—p. 36.
- Bone Regeneration. G. Levander.—p. 40.
- *Comparative Tissue Thermometry. O. Lippross.—p. 49.
- *Significance of Serum Heating Test for Diagnosis of Carcinoma. W. Zunke.—p. 53.

Comparative Tissue Thermometry.—Lippross discusses the technic of tissue thermometry and its superiority for diagnostic purposes over the usual skin thermometry. Tissue thermometry is done by means of an apparatus employing thermoneedles which are, preferably, thrust into the musculature of the calf of the leg and the ball of the hallus. (The lowest temperature in the tissues was found in the latter area; the highest [102.2 to 104 F.] in the liver.) "Comparative tissue thermometry" is defined as occurring when similar anatomic parts of the two lower extremities are measured simultaneously. Four punctures are required, which are said not to be particularly painful after some skill in applying the technic is attained. Single tissue tests, however, are often not sufficient. Tissue thermometry seeks (1) to ascertain whether pathologic conditions capable of thermometric determination exist at all and whether the index is higher in the calf than in the hallus area and (2) to institute special diagnostic tests in accordance with the temperature differences between the calf and the hallus index observed on the same side of the body. The author by this method was able to demonstrate especially low temperatures in the hallus ball tissue with serious circulatory disturbances in the toe joints of healthy persons of asthenic build. The subjective feeling of cold feet was rarely in keeping with objective measurements. Two cases will indicate the difference in accuracy between tissue and skin thermomeasurements. Sympathectomy performed for thromboangiitis obliterans showed, two months later, a 1.5 C. higher skin temperature in the affected limb. Two years later no difference was observed on the two sides. Tissue thermometry, however, disclosed a difference of from 5 to 6 C. in the hallus ball area. In a case of intermittent claudication lasting ten years sympathectomy was contraindicated because no comparative difference in the skin temperature on the two sides could be observed. Tissue thermometry, however, disclosed a considerable regulatory dysfunction in one member. Thermometric tests included cold and hot baths, with the legs kept out of the water to permit uninterrupted tissue examination. The author believes that this technic represents progress in the functional diagnosis of pathologic conditions in the lower extremities. More deeply situated tissue is not subject to numerous external factors, hence permits a more exact measurement and affords a better understanding of the regulatory processes of the body. This technic makes possible not only the progressive measurement of the temperature of the different tissues and their fluctuation under certain circumstances but also the simultaneous measurement of the temperatures of these tissues.

Serum Heating Test for Diagnosis of Carcinoma.—Zunke employed Kürten's technic for the detection of carcinoma in 531 cases involving 891 double tests and retests. According to Kürten, when 1 cc. of human blood serum is slowly heated over a burner in a small test tube, two reactions will occur: either (type I) the albumins will precipitate and adhere to the sides of the tube, at the same time releasing an opalescent fatty salt solution, or (type II) the total serum will coagulate and remain in this condition in spite of continued heating. The first reaction characterizes predominantly the serums of healthy as well as ill persons. The second is found in the serums of subjects with malignant tumors and in some cases of acute and chronic disease. However, Kürten found that on the subsidence of the acute stage the serum would give a type I reaction. In 492 of 531 of Zunke's serum specimens, heating tests and retests confirmed clinical or postmortem diagnosis. In the remaining cases, operation or necropsy could not be performed or the patients could not be observed long enough. Forty-six cases involved carcinoma. Coagulation type I in these was observed only four times, all in patients previously roentgenologically treated. Four hundred and thirty-seven were nontumor cases; 43 of these, the majority pneumonia (15), showed type II reaction. Lobar pneumonia invariably gave a type II reaction in the acute stage and a type I reaction during subsidence. Like Kürten, Zunke found that the serum of carcinomatous subjects and those affected with certain acute and chronic diseases presented a type II coagulation. The diagnostic value of

the serum test was not impaired when clotted or centrifugated serum, refrigerated for a few days, was used; hemolytic serum, however, proved unreliable. The author believes that Kürten's technic employed routinely may be of value in discovering the possible presence of carcinoma, especially in cases in which more complicated cancer examinations are in order. The technic, simple as it is, needs to be carried out with the greatest care. Otherwise the results will be vitiated.

*The Problem of Carcinoma. W. Brünings.—p. 117.

Frostbites. F. Bering.—p. 123.

Food Poisoning by Means of Duck Eggs. H. Müller.—p. 125.

Albers-Schönberg Marble Bone Diseases. H. Kramer.—p. 132.

Problem of Carcinoma.—Brünings, working on the theory that neuroendocrine disturbances of the carbohydrate metabolism may be etiologically involved in carcinoma, attacked the problem by combining a dietary regimen poor in carbohydrates with insulin therapy in 14 cases of nasolaryngologic cancer, only 1 of which was associated with diabetes. The carcinomas selected were those in hopeless cases but susceptible of being viewed, together with their metastatic invasion of the lymph nodes, macroscopically and the tissues of which could be excised for microscopic study. In all cases, general as well as local, amelioration was temporarily observed, varying from arrest of tumor growth to total macroscopic disappearance of the tumor and its metastases. Body weight invariably increased in the first weeks, slowly falling after from one to two months but rarely below initial levels. This improvement lasted from two to three months, after which a reactivation of tumor growth set in and a tendency to necrosis, pain and hemorrhages. Further treatments were unavailing. Under the microscope, in most cases, the reduction of malignant growth turned out to be only a quantitative diminution; excised tumor portions showed degenerate cancer cells. No essential modification of insulin tolerance was observed, nor subjective or objective damage due to hypoglycemia. The tolerance limits varied considerably in different persons. If primary tumor did not promptly respond to the therapy, roentgen irradiation was at once instituted. In 2 cases in which the combined treatments had already clearly brought about tumor recession, it was noted that on withdrawal of the insulin the malignant condition was stimulated to new life or that the tumor-retarding protection had ceased. The same observations were made in 2 other cases in which only the diet had been administered for ten days. Even a combined therapy in which insulin dosage was pushed to the individual limits of tolerance yielded no information as to the effect of insulin, or of any unknown factor in insulin, on carcinoma. The author believes that a causal connection exists between carcinoma and carbohydrate metabolism which needs to be further investigated. The favorable results temporarily obtained lead him to think that combined dietary and endocrine treatments may be of value in aiding diagnosis when carcinoma is suspected, in conditioning the patient for an operation to be performed and as an adjuvant of roentgen therapy.

Differential Diagnosis of Pathologic Changes of Sella Turcica in Roentgenogram. H. Greving.—p. 353.

*Cerebrospinal Fluid in Multiple Sclerosis. O. Seuberling.—p. 359.

Intracranial Pressure After Brain Operations.—Sprockhoff points out that, in some patients who have undergone surgical intervention on the brain, the formation of cerebrospinal fluid does not keep pace with the resorption, and the result is deficiency and hypotension of the fluid. He lists 11 cases in which there was such postoperative hypotension.

With the exception of 2 patients who had undergone removal of the squama occipitalis, all had supratentorial defects of the cranium. The patients have headache and are restless and irritable before the hypotensive state develops. The sensorium becomes dulled; slight rigidity of the neck, fatigue, lassitude and nausea develop. There usually is a mild hyperthermia and hyperpnea, but the blood pressure and the pulse remain normal. Pallor is occasionally seen. If there is a cranial defect, retraction is noticeable. The pupils become rigid, and reflexes abolished. Respiration becomes snoring and approaches the Cheyne-Stokes type. This comatose condition may also develop without the prodromal signs. The hypotensive condition does not always lead to complete coma. Differentiation from increased intracranial pressure (brain swelling arachnoiditis) may be difficult, particularly if there is no cranial defect. The proof that the described clinical symptoms are produced by hypotension in the fluid space is furnished by the fact that intraspinal administration of physiologic solution of sodium chloride promptly counteracts the acute symptoms. If too much fluid is introduced, the skin over the cranial defect will bulge and the undesirable tension may have to be counteracted by another puncture. On the other hand, the retraction in the defect may recur after the filling so that intraspinal injection has to be repeated. This instability shows that the lack of fluid is not the only cause but that there is also a disturbance in the dynamic equilibrium between formation and absorption of the cerebrospinal fluid. For this reason filling of the fluid space is not sufficient. As few punctures as possible should be made, because every puncture that is not required to counteract acute hypotension or excess pressure retards the regulation. It is necessary to aid the organism in maintaining normal pressure. Fluid should be given in generous quantities; in the mild cases by mouth, in the severe cases by intravenous infusion of sodium chloride or dextrose solutions. The author supported the oral administration of fluid with caffeine in order to increase the blood perfusion of the choroid plexus and thereby stimulate the production of the cerebrospinal fluid. Since erect posture promotes absorption of the cerebrospinal fluid and favors decrease in pressure, this posture should be avoided in hypotension, contrary to the general rule in postoperative treatment. Patients with hypotensive conditions complain of headaches which do not differ from those caused by increased intracranial pressure except that they cannot be improved by the withdrawal of spinal fluid but require intraspinal administration of fluid. The prolonged headaches complained of after lumbar puncture by psychopathic persons or by those with weak sympathetic nervous systems are probably of this hypotensive type. Two of the author's patients had chronic hypotensive symptoms, suffering for years with severe headaches. Both had considerable defects in the cranium and, having noticed that greater severity of headaches was accompanied by greater retraction, they requested plastic repair, after which they were free from complaints. Reduced secretion is the decisive factor, and this in turn must be due to impairment of the plexus. Various causes, such as senile involution, diffuse atrophy of the brain, prolonged existence of internal hydrocephalus, reduced blood pressure and general exsiccation may be responsible. The author points out that some employ an exsiccating preoperative treatment in order to avoid postoperative swelling of the brain. This preoperative exsiccation proved its value. The author does not reject the method but emphasizes that it should be used with discrimination, for, if it is employed in all cases, postoperative hypotension will be more frequent. It should not be employed in cases in which the previous history or clinical aspects indicate a tendency to hypotension.

Cerebrospinal Fluid in Multiple Sclerosis.—Seuberling reports the serologic picture of cerebrospinal fluid in 140 cases of multiple sclerosis observed at the neurologic clinic of the university of Würzburg. The results obtained, together with those of three other German clinics, suggest that the cerebrospinal fluid of 75 per cent of patients with definitely established multiple sclerosis shows pathologic changes. The author was

able to corroborate the observation of several other investigators that a correlation exists between changes in the cerebrospinal fluid and severity of the multiple sclerosis. Pathologic alterations of the cerebrospinal fluid occurred twice as frequently in patients with severe multiple sclerosis as in those with a mild form. During the acute attack only 2 per cent of the fluids were normal. The largest percentage of normal fluids was obtained from patients whose disease had lasted less than a year. In the course of the first attack 98 per cent of the patients show pathologic changes in the cerebrospinal fluid, but in more than one half of these the fluid becomes normal later on. In patients with chronic multiple sclerosis the fluid is much less likely to become normal after an exacerbation. Efforts have been made at the author's clinic to develop a specific reaction for multiple sclerosis by paying particular attention to the lipid metabolism and the lipolytic ferments in the cerebrospinal fluid. No characteristic sign or behavior has thus far been detected. Spinal punctures have not been found harmful at the author's clinic except for occasional retention of urine for about a day. Punctures should not be made in cases of multiple sclerosis in which foci are suspected to exist on the floor of the fourth ventricle and in which bulbar and vagal symptoms appear. The author observed a coma of several days' duration following a puncture in a case of this type.

Connection Between Scleroderma and Progeria. B. Müller-Hess.—p. 96.

*Can Skimmed Milk Be Rendered Antirachitic by Irradiation? K. Scheer.—p. 104.

Therapy of Epidemic Meningitis.—Boehneke compares 44 cases of epidemic meningitis in which serum therapy was employed with 46 in which serum and a sulfanilamide preparation were used. There were 30 fatalities among those treated with serum, a mortality of 68 per cent. In the 46 cases treated since 1938 in which a sulfanilamide preparation was given in addition to the serum, the mortality rate was reduced to 8.6 per cent. Although the two groups were treated in different periods and the age distribution was slightly different, the author thinks that this does not explain the difference in the mortality rates. The sulfanilamide preparations used were protosil album and albid (\equiv acetylsulfanilamide). Sulfanilamide was given in the first 20 of the 46 cases and acetylsulfanilamide in the other 26. The author prefers the latter preparation because it can be given in concentrated solution by intravenous, intramuscular and intraspinal injection and because its toxicity is less than that of sulfanilamide. Another advantage of acetylsulfanilamide especially important in meningitis is that it readily passes the cerebrospinal barrier. Acetylsulfanilamide proved more effective. Of the 20 cases in which serum and sulfanilamide was used, 4 had a fatal outcome, whereas among the 26 treated with serum plus acetylsulfanilamide there were no fatalities. The author concludes that the treatment with meningococcus serum plus acetylsulfanilamide is the method of choice in epidemic meningitis.

Irradiation of Skimmed Milk.—Scheer points out that a considerable portion of the total cholesterol content of milk is combined with the proteins, particularly lactalbumin. He deduces that the antirachitic power of irradiated milk is not limited to its fat content. Thus it seemed of interest to determine whether skimmed milk can be rendered antirachitic by irradiation. From comparative experiments with irradiated whole milk and irradiated skimmed milk he learned that irradi-

ated skimmed milk has an antirachitic action which will cure a severe florid rickets, although the time required for such cure is somewhat longer than with the use of irradiated whole milk.

*Prophylaxis for Diphtheria Among Navy Men. K. Kariya, K. Yamamoto and T. Shibata.—p. 137.

*Report of Necropsy on Pellagra. M. Nakamura, C. Hamada and H. Oriuchi.—p. 179.

Diphtheria Prophylaxis for Sailors.—Kariya and his associates found positive Schick reactions in 5 per cent of the entire crew below the rank of noncommissioned officers on a cruiser. After ascertaining the probable freedom from sensitivity by means of the Moloney test in these Schick-positive reactors, they administered a total of diphtheria anatoxin varying from 1.1 to 1.5 cc. in three divided doses at weekly intervals (0.2, 0.5 and 0.8 cc.). From careful statistical observations as to the incidence of diphtheria as well as of acute tonsillitis and acute laryngopharyngitis on the ship, the authors found diphtheria to have been completely eliminated and acute tonsillitis and pharyngitis greatly reduced among these men during the twelve months following the prophylactic immunization. Schick tests then repeated on these men gave, without exception, negative reactions. From these results it is recommended that diphtheria anatoxin, in the amount of 1.5 cc. and administered in three divided doses at weekly intervals, be employed as an effective measure in the prophylaxis of diphtheria.

Pathology of Pellagra.—Nakamura and his associates give a detailed report on the necropsy in a case of pellagra occurring in a sailor with a history of chronic gastrointestinal disturbance. The patient had complained of vague epigastric pain, numbness of the lower extremities and slight edema, all suggestive of beriberi. The roentgenogram revealed a mild degree of gastroparesis, and the gastric acidity was extremely low. Except for a slight leukocytosis with a left shift, blood counts and serologic tests were essentially negative. Urinalysis showed the presence of albumin and urobilinogen. After a slight improvement the patient was allowed to go fishing at the hospital lagoon, and the sunlight to which he was thus exposed caused his skin to become erythematous with the development of a tingling sensation; later the skin became brownish with a bran-like desquamation. These cutaneous lesions failed to clear up and turned into well demarcated copper hued areas in the middle of the chest, on the nose, and over the knees and dorsum of both feet. Urinalysis at this time revealed the presence of indican in addition to urobilinogen. Administration of high dosage of vitamins B₁ and B₂ failed to produce improvement. Necropsy revealed marked atrophy of the heart, kidneys, liver and intestine, excessive dilatation of the stomach with evidence of atrophic gastritis, and numerous hemorrhages in the entire gastrointestinal tract. There was definite scar formation in the pachymeninges as well as in the leptomeninges of the frontal lobe, together with a considerable degree of round cell infiltration. Microscopically the myocardium was greatly atrophied and the liver also generally atrophic with fibrosis of Glisson's capsule and cellular infiltration. The muscle fibers near the pylorus of the stomach were slightly hypertrophic with round cell infiltration in the interstitial spaces, most pronounced near the nerve fibers. A few Russell's bodies were seen in the mucosa, which was highly atrophic. The intestinal mucosa was also atrophic and the follicles were increased in number, with evidence of extravasation of blood around the capillaries.

*Studies on the Function of Hypophysis in Carbohydrate Metabolism. T. Sakai.—p. 189.

Hypophysis in Carbohydrate Metabolism.—Sakai started his investigations on the function of the hypophysis in carbohydrate metabolism by first observing sugar assimilation in 14 cases of acromegaly, in 64.3 per cent of which he found glycosuria. In over half of these cases the glycosuria was found to be renal in nature, with a spontaneous and markedly fluctuat-

ing elevation of the excretory threshold. In all cases in which glycosuria was present the duration of the disease had been more than ten years. In only 3 cases was there fasting hyperglycemia, with a definite lowering of sugar tolerance. Sakai believes that hyperglycemia in acromegaly is extrainsular in origin. The second phase of his studies deals with the observations of sugar metabolism in patients with disturbance in the anterior pituitary lobe. Of 9 cases of dwarfism, 4 cases of cachexia, 3 cases of polyglandular deficiency, 2 cases of eunuchoidism and 3 cases of dystrophia adiposogenitalis the majority exhibited disturbances in sugar metabolism, such as delayed restoration of normal blood sugar level following alimentary hyperglycemia, slow development of epinephrine hyperglycemia, glycosuria and relevation of both sugar tolerance and the excretory threshold. In a further study of sugar metabolism in 6 cases of diabetes insipidus the author found practically no evidence of disturbed sugar metabolism. In 10 cases of hypophyseal dysfunction without association of endocrine disturbance, Sakai found 2 patients presenting symptoms of anterior lobe dysfunction during pregnancy with renal glycosuria, which he explained on the basis of the pregnancy-cell-nodule hypothesis of Erdheim. In the experimental animal (rabbit) the author saw an immediate elevation of the sugar excretion threshold by the intravenous or subcutaneous injection of gonadotropic extract from pregnancy urine. One or one and a half months after the subcutaneous injection the threshold was gradually lowered, and repeated administrations at this stage no longer produced relevation. Identical results were obtained with a similar injection of adrenal cortex extract. These observations prove that elevation of the renal threshold produces marked alimentary hyperglycemia and that the metabolic function is at its best when the renal threshold is low.

Benign Ureteral Tumors. T. Olovson.—p. 469.

Serotherapy in Peritonitis.—Bohmansson and Norup state that acute septic perforation peritonitis has been treated at their hospital in Örebro with serum since 1934. In 1935 one of them reported at a meeting in Copenhagen that until then serotherapy had not reduced the mortality of peritonitis. On the basis of subsequent observations, however, they arrived at a different conclusion. They found that as long as small doses were used, namely from 20 to 40 cc., the mortality did not decrease. During the ten year period from 1929 to 1938 the mortality was above 40 per cent. The authors restrict the term diffuse septic peritonitis to cases which show a much impaired general condition, diffuse abdominal tenderness, peripheral circulatory disturbances, severe impairment of the intestinal function and free purulent exudate in the abdomen either of putrid odor or yielding bacteria by culture, the culture being made immediately after opening of the abdomen, before the focus is touched or exploration has been done. Only cases which fulfilled all these requirements have been counted, and this explains the high mortality. During 1939 and 1940 the authors used much larger doses of serum. They now introduce at the time of operation 60 cc. into the abdomen and 40 cc. intravenously, and in exceptional cases supplementary doses are given on the following days. This serum therapy was combined with sulfanilamide medication, which is continued for from four to five days. In this way it was possible to reduce the mortality to 6.3 per cent. The material on which the present report is based comprises 3,787 cases of gangrenous appendicitis, of which 626 had perforated before the operation and 210 cases were

complicated with diffuse septic peritonitis. The authors conclude that with large doses of serum combined with sulfanilamide it will be possible to lower the mortality in diffuse peritonitis but that this treatment is of no particular value in circumscribed peritonitis. Anaphylactic shock is rare with these large doses not only when administered under general anesthesia in the course of operation but when given under spinal anesthesia as well.

Population and Clinical Statistics of Pulmonary Infections. J. Rudebeck.—p. 293.

Acute, Nonfatal Cocaine Poisoning: Four Cases. N. Alwall.—p. 335.

Production of Pernicious Anemia.—Petri and Jensenius review results of other investigators and their own on the operative measures carried out on the stomach in an attempt to produce pernicious anemia. Various anemic conditions (depending on the species of animal and the type of operation) have developed but in none of the many experiments has pernicious anemia been produced successfully, with the simultaneous appearance of the typical characteristics: hyperchromic megalocytic anemia, hyperplasia of the bone marrow and capacity for reaction to liver therapy. Nor has this been accomplished after toxic or other injurious treatment of the animals operated on. In a few cases a blood picture resembling pernicious anemia has been observed. In gastrectomized pigs a severe chronic and finally fatal pellagra has appeared. The condition also appeared in other species submitted to such treatment. The frequency with which spontaneous anemias have appeared in the dog has varied somewhat: after total gastrectomy in 78 per cent, after subtotal gastrectomy or resection of the stomach in 59 per cent and after "isolation of the stomach" in only 27 per cent. In contrast to this, after resection of the fundus or pylorus, anemia developed in 100 per cent of the cases. The less frequent occurrence of anemia when the stomach was made to form a closed pocket suggests the hypothesis advanced by Morris and his collaborators (1933): that the stomach might have some endocrine substance with an antianemic function. In dogs, swine and rats, the more common types of anemia have been hypochromic anemia (most frequent) and "isolated hypochromia." In the monkey only hypochromic anemia has been diagnosed. There is some difference in the time it takes anemia to develop after various operations. Animals seem to become anemic more rapidly after total gastrectomy and resection of the fundus than after resection of two thirds of the stomach. Accordingly removal of the fundus area may possibly prove most decisive for the development of the anemia. In dogs remission has been observed especially after resection of the fundus and in swine only after resection of the pylorus. The authors discuss the views concerning the failure to produce pernicious anemia experimentally by operations on the stomach. The views have varied owing to the variable stand of the clinicians with regard to the antipernicious anemic activity exerted by various parts of the digestive tract and also reflecting in part the uncertainty which recently has asserted itself with regard to the site and mode of formation of the active liver principle. Before the studies are extended further the authors believe that the biologic foundation for a positive result must be cleared up. They conclude that since the operations used so far have not resulted in pernicious anemia—despite the fact that animals appear to possess the biologic foundation for such a condition—two possible causes suggest themselves: (1) either the site of formation of the intrinsic factor is not interfered with sufficiently by the operation or (2) the correctness of Castle's theory has to be questioned.

Book Notices

Essentials of Dermatology. By Norman Tobias, M.D., Senior Instructor in Dermatology, St. Louis University, St. Louis. Cloth. Price, \$4.75. Pp. 497, with 143 illustrations. Philadelphia, Montreal & London: J. B. Lippincott Company, 1941.

Tobias presents an excellent compact synopsis on dermatology in which, "as far as practical, each disease is discussed from the standpoint of internal medicine." The subject matter of the book is divided into thirty sections, e. g. the erythema group, the eczema group, drug eruptions, the toxic bullous diseases, diseases due to physical agents, diseases due to psychic and nervous disorders, tuberculosis of the skin, the deep infective dermatoses, syphilis and malignant growths of the skin, the metabolic disorders, pigmentations, the lymphoblastomas, the erythrodermias and a section on dermatologic therapeutics. All the subjects are discussed well in a succinct manner with a good literary style. Under metabolic dermatoses the avitaminoses are discussed. The accepted newer concepts in dermatology are incorporated in the discussions in the book. In the first section, on basic survey, under etiologic factors the author discusses atopy and nonatopic allergy together with drug, bacterial and physical allergy. Under diagnostic methods he mentions briefly those important pertinent procedures of interest to dermatologists and to the practitioner interested in diagnosis in dermatology. In this section there is also an excellent discourse on the cutaneous manifestations of systemic disease. There are one hundred and thirty-eight halftone illustrations of dermatoses, of good quality. The book is in convenient small form printed on good paper with a clear legible type and is an excellent addition to the compact textbooks dealing with the essentials of dermatology and should have a place in the library of students and general practitioners who desire to acquaint themselves with the basic facts of dermatology.

Sex Variants: A Study of Homosexual Patterns. By George W. Henry, M.D. With Sections Contributed by Specialists in Particular Fields. Volumes I and II. Sponsored by Committee for the Study of Sex Variants, Inc. Cloth. Price, \$12.50, per set. Pp. 546; 549-1179, with 66 illustrations. New York & London: Paul B. Hoeber, Inc., 1941.

In 1935 a committee was established to study sex variants. The membership included some of the most distinguished workers in this field, associated with experts in biology, psychiatry, genetics and similar subjects. Arrangements were made to secure interviews with a considerable number of persons known to be homosexual, and in these two volumes are reported a complete study of 80 persons of this type. For each there is a genetic chart, a record of general impressions, the family background, the personal history, the physical examination, including a special study of the sex characteristics, and a complete roentgenologic study, then a comment and a summary.

At the end of the second volume there appear a number of collected studies. The author is convinced that the sex variant is a by-product of our civilization—an expression of inability to meet the responsibility of establishing and maintaining a home which involves the rearing of children. Unfortunately, investigations made in primitive civilizations seem to indicate that in such instances as well the sex variant is not infrequent.

An interesting observation is the following: "All persons who manifest violent emotional reactions to the sex variant warrant serious consideration. Such persons may be reacting to personal experience or they may be on the defensive lest they disclose their own unconventional desires and impulses."

Another significant conclusion is the following: "There is no adequate substitute for well adjusted parents. The supervision of the psychosexual development and conduct of children is one of the greatest responsibilities of parenthood. Servants, siblings and other relatives as well as friends often contribute to the psychosexual distortion of children. In our present state of ignorance regarding sexual matters, a parent who is fully prepared to undertake the responsibility of supervising the psychosexual development of his children is a rare person."

There are altogether five and one-half pages of these impressions, which should be read with care by every one who may be concerned with this problem. It is indicated that the law has been a conspicuous failure in handling this serious situation.

Society has no solution for the problem. Scientific approach would seem to be the only answer.

Special supplements to the book include a series of masculinity-femininity tests of men and women, some full page illustrations of physical characteristics, scientific studies of roentgen anthropometry, a gynecologic study by Dr. Dickinson and a series of drawings, and finally a study of the language and vocabulary of sex variants.

The book is a most useful scientific contribution to the subject, obviously to be restricted in its distribution to those with a legitimate scientific interest.

A Manual of Maladies Influenced by Oxalic Acid Poisoning viz. Industrial Myositis Fibrosa, Occupational Schizophrenia and Experimental Wassermann and Kahn Tests. By Abel C. Anthony, B.S., M.D. Cloth. Price, \$2. Pp. 85, with 17 illustrations. Chicago: The Author, 1941.

The temptation is to label this badly printed booklet both as confused and as confusing. These things this book is, but deep within its shortcomings there may be some fundamental disclosures warranting more careful inquiry. The book holds and claims to prove that oxalic acid is one cause of myositis fibrosa, is in some instances a specific cause of schizophrenia and that the presence of oxalic acid in the body upsets the diagnostic serologic reaction to the point that faulty diagnoses of syphilis are made. The author's material chiefly is derived from workers of a public carrier company in Chicago, where oxalic acid was one constituent of a cleaning fluid for toilet fixtures, cuspidors and wash basins. The author's arguments are colored by unveiled antipathy for the employer and the medical activities of the staff of an unnamed hospital designated as "carrier elected hospital." He provides no quantitative evidence as to exposures either for his patients or for experimental animals. The diagnosis of industrial oxalic acid poisoning apparently rests on qualitative exposure plus the presence of quantities of oxalate in the urine, blood and certain tissues. Anthony does not overlook the fact that normal urine may contain in the daily output from 30 to 40 mg. of oxalic acid (oxalates?) and that this amount may be augmented by a diet that includes rhubarb, tomatoes, asparagus, spinach or sorrel. He however possibly overlooks or minimizes the fact that oxalate crystals may be demonstrated in some normal tissues at all times.

Despite the author's concepts of scientific possibilities from oxalic acid poisoning, his evidence distressingly defeats his objectives. For example, at one point it is set forth that the minimum lethal dose for human beings is 60 grains, but at one point the author in presenting a finding of 0.275 mg. of oxalic acid in a 140 mg. forearm biopsy specimen taken from a 140 pound woman has furnished basis for the calculation that if the oxalic acid was equally distributed over the body at that moment there must have been a total body content of 1,947 grains. By all the rules this patient should have been dead some years earlier, since apparently the last exposure to oxalic acid was more than two years earlier.

Diseases of the Digestive System: A Text-Book for Students and Practitioners. By Eugene Rosenthal, M.D., Lecturer in the Medical Faculty, Royal Peter Pázmány University, Budapest, Hungary. With a preface by R. J. V. Pulvertaft, M.D., F.R.C.P., Reader in Pathology, University of London, London. Cloth. Price, \$8.50. Pp. 394, with 234 illustrations. St. Louis: C. V. Mosby Company, 1940.

This is a rather unusual book. It is essentially an eclectic presentation of lectures on the digestive system and a mass experiment in mnemonics. It is difficult to evaluate the lavish use of color and geometric design of the author's diagrammatic attempts to fix signs, symptoms and their association for the reader. Undoubtedly this method of presentation was developed by years of teaching experience. Whether it will have the same value in a textbook as it had in the classroom can be decided only by the reader. The text is divided into five chapters covering diseases of the esophagus, diseases of the stomach and intestinal tract, diseases of the liver and biliary tract, diseases of the pancreas and diseases of the peritoneum. The material is not an epitomized version of a textbook on this subject. It apparently represents the author's rich clinical experience carefully organized and dogmatized for effective presentation. The author's style is simple and practical. Pathology, diagnosis and treatment are concisely but

effectively presented. The frequent use of colored diagrams, charts and roentgenograms is a distinct aid to the reader in fixing the factual data. This is a book that the physician can profitably purchase though he may possess other textbooks on the digestive system. It is a painstaking effort by a trained clinician and teacher.

Common Mistakes of Surgery in India and How to Avoid These: A Practical Handbook for the Young Surgeon, the General Practitioner, the Hospital Medical Officer and the Surgically Minded Student. By Lt. Col. A. N. Palli, O.B.E., F.R.C.S., M.R.C.O.G., Senior Surgeon, Chittaranjan Sevo Sadan Hospital, Calcutta. Cloth. Price, \$3. Pp. 352, with illustrations. Calcutta: Book Company, 1940.

The common mistakes of surgery in India and modern surgical practice are discussed in this book, written by a civil surgeon who has had long experience in Bihar and Orissa. It contains chapters on anesthesia in Indian practice, antiseptics, fractures and joint injuries, head injuries and cranial surgery, eye, ear, nose and throat, abdominal injuries and operations, rectal and genitourinary surgery, gynecology and modern treatment with sulfonamides and its abuses. The field of surgery appears to be covered extensively, giving the various methods of treatment and the author's views and knowledge gained through eminent surgeons who were his teachers. The book has been written for the general practitioner, the physician in charge of a small hospital, the young surgeon and the student interested in surgery. The style of the book, however, is poor and many words are misspelled.

Getting Ready to Be a Mother. By Carolyn Conont Van Blarcom. Revised by Hazel Corbin, General Director Maternity Center Association, New York. Fourth edition. Cloth. Price, \$2.50. Pp. 190, with 90 illustrations. New York: Macmillan Company, 1940.

The general practitioner, the obstetrician and the pediatrician often may find it advantageous to have a mother familiarize herself with the principles of conduct during and after pregnancy. This book may be recommended with confidence for this purpose. It should aid mothers materially in carrying out the physician's recommendations during pregnancy and in managing the infant during the important early weeks. As is true with many such books, certain ideas are advanced which may differ in point of view from those generally accepted, but these are presented only occasionally. For example, the suggested method of administering cod liver oil is not that which is generally approved. The makeup of the book is excellent and the illustrations are more than satisfactory; the book is clear, simple and interesting.

Hutchison's Food and the Principles of Dietetics. Revised by V. H. Mottram, M.A., Professor of Physiology at King's College of Household and Social Science, University of London, and George Graham, M.D., F.R.C.P., Physician to St. Bartholomew's Hospital, London. Ninth edition. Cloth. Price, \$6.75. Pp. 648, with 30 illustrations. Baltimore: William Wood & Company, 1940.

This book first appeared in 1900. The present edition indicates better than words its past value and usefulness to physicians and others interested in dietetics. The present editors realize that there is now little need for an encyclopedic book on dietetics which lists table after table of nutritive values of innumerable foods and that the emphasis now is on the "newer knowledge" of nutrition. From these two points of view, Mottram and Graham have extensively revised or in many instances completely rewritten the chapters, which have been rearranged into four sections: diet in normal life, the nature of foods, the principles of feeding in infancy and childhood, and diet in the treatment of disease. This revision brings this classic book on dietetics to be an authoritative expression of that which is both old and new. It should prove to be a useful book for daily reference by all interested in nutrition.

Les syndromes douloureux de la région épigastrique. Par René A. Gutmann, médecin des hôpitaux de Paris. Préface du Professeur A. P. Gosset. Tomes I et II. Third edition. Paper. Price, 495 francs. Pp. 750; 737, with 316 illustrations. Paris: G. Doin & Cie, 1940.

These two volumes compose an exhaustive treatise on maladies affecting the epigastric region. (The pancreas is included in a separate volume.) The work is richly illustrated with nine hundred and three roentgenograms and four hundred and thirteen diagrams. Emphasis is placed on the importance of detailed,

accurate history taking and thorough physical examination as aids to exact diagnosis. Contents include discussion of ulcers of the stomach and duodenum, cancer and gallbladder disorders. The perivisceral syndromes, dyspepsias (allergic, menstrual, nervous), hemorrhages, gastritis and duodenitis, avitaminosis, gastric crisis and malformations of the diaphragm and stomach also are discussed. Treatment is outlined in each section. This treatise should be useful to internists who read French. The sections on gastroscopy are limited. In general, however, there is a wealth of detail. The major criticism of the book is its length. The emphasis, from the diagnostic point of view, is far more detailed than the usual American work on gastroenterology. Some of the newer fields, as avitaminoses and gastrointestinal allergy, are treated at length.

Die Bakteriologie der Salmonella-Gruppe. (Typhus-Paratyphus-Enteritidis-Gruppe). Von F. Kauffmann, Abteilungsleiter am Staatlichen Serum-Institut Kopenhagen. Paper. Price, 29 Danish kroner. Pp. 393. Copenhagen: Einar Munksgaard, 1941.

The Salmonella or paratyphoid group of bacteria has been studied extensively by Bruce White in England and by Kauffmann in Copenhagen. By means of the agglutinin absorption test these strains have been studied and classified. The number of antigens in a given specific species may be many and thus the antigenic components of the group as a whole form a complex mosaic pattern. At the State Serum Institute in Copenhagen an international Salmonella center has been established and financed by the Commonwealth Fund. This center will supply gratis to national Salmonella centers in various countries all serums and cultures necessary for serologic diagnosis. Furthermore the international Salmonella center in Copenhagen is prepared to examine doubtful cultures without charge. Kauffmann has brought up to date in this report the more recent developments in this field. This book can be recommended to laboratory workers who are attempting to classify strains of Salmonella or to bacteriologists engaged in this field of research.

The Pharmacology of Anesthetic Drugs: A Syllabus for Students and Clinicians. By John Adrien, M.D., Instructor in Anesthesia, New York University College of Medicine, New York. Second edition. Fabrikoid. Price, \$3.50. Pp. 86, with illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas, Publisher, 1941.

The pharmacology of anesthetic drugs is displayed in a unique fashion, making possible brevity with relative completeness. The author has based his statements either on experience or on statements that are considered not to be controversial that have been published elsewhere. The useful items of interest are included in the briefest possible form, such as a glossary, a bibliography and formulas of drugs, together with some laboratory results which fortify the statements as to clinical results. It is a book which those interested in anesthetic drugs will find valuable to have at hand for reference or for a quick review of the action of anesthetic drugs.

Counseling the Handicapped: A Manual on Aptitudes and Their Discovery and Interpretation. By Holland Hudson, Director, Rosetta Van Gelder, Rehabilitation Assistant, Rehabilitation Service. Paper. Pp. 55. New York: National Tuberculosis Association, 1940.

The National Tuberculosis Association recognizes the importance of occupational therapy, has studied the available tests of aptitude and presents them in a reasonably priced manual with full instructions as to how the various tests may be performed. A booklet of this kind has value for counselors in rehabilitation.

War Wounds and Injuries. Edited by E. Fletcher, M.A., M.B., M.R.C.P., Physician, Queen Mary's Hospital for the East End, London, and R. W. Riven, F.R.C.S., Surgeon to Out-Patients, French Hospital, London. With a foreword by Lord Horder. Based on articles in the "Post-Graduate Medical Journal" (Fellowship of Medicine). Cloth. Price, \$5. Pp. 262, with 57 illustrations. Baltimore: William Wood & Company, 1940.

This small volume contains articles dealing with practically all aspects of war wounds and injuries except burns and sepsis. Without entering into extensive theoretical discussions or attempting a presentation of controversial points of view the information offered represents the essence of experience gathered during the war of 1914-1918 as well as that more recently acquired in the present war. The contribution is preeminently practical and will undoubtedly prove of value to the younger surgeon called to military duty.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

YELLOW FEVER

To the Editor:—Please give me information about yellow fever, which I cannot obtain from the sources otherwise available to me. 1. In the absence of complete postmortem examination, is the diagnosis possible through examination of a "core" of the liver tissue obtained with a tracer? 2. How is diagnosis established in convalescent persons? 3. How is a vaccine obtained without identification of the causative organism? 4. How is the rhesus monkey utilized in the study of yellow fever?

Hermann B. Gessner, M.D., New Orleans.

ANSWER.—1. Yes, with small chance of error, if an adequate specimen, like that obtainable with the "viscerotome," is preserved in solution of formaldehyde U. S. P. diluted 1:10 and examined by a pathologist familiar with yellow fever.

2. For certain diagnosis in cases with recovery, 10 cc. of blood serum should be obtained in the first three or four days of illness and again three weeks after onset or later. The first specimen may be highly infectious and should not touch the skin of the operator. Each specimen should be tested in the laboratory in mice for protective yellow fever antibodies. If the first specimen gives a negative and the second a positive result, the illness is yellow fever. If only the convalescent serum is available a positive result shows merely that the person has had yellow fever at some time, but a negative one rules out yellow fever.

3. The causative agent is a filtrable virus which has been known and studied since 1927. The vaccine most widely used consists of a strain (17 D) of the living virus modified through long cultivation in chick embryo tissues.

4. The rhesus monkey is used in recovering yellow fever virus from man by injections of blood, in studying the effects of the virus in an animal reacting about as man does and in testing the vaccine for safety and effectiveness.

UNDULANT FEVER OR OTHER GASTRO-INTESTINAL DISEASE

To the Editor:—A woman aged 63 complained of headache, general aching, nausea and epigastric distress, together with a teasing cough and slight coryza. The temperature was 100.4 F. Since a mild epidemic of influenza was prevailing at the time a diagnosis of influenza was made, and under appropriate therapy the temperature dropped to normal and the respiratory symptoms cleared. However, the headache, epigastric distress and backache have persisted unchanged up to the present (six weeks) and a further history disclosed that she has had similar complaints over the past six months. There is an indefinite mass palpable in the epigastric region to the left of the midline, with moderate tenderness. There is a less marked tenderness at the right costal margin over the gallbladder region. The skin is dry and scaly, with a slight icteric tint to the sclerae. The rest of the physical examination is negative. There is a definite retention in the stomach, and she is unable to take more than a few mouthfuls of food at a time. Gastrointestinal roentgenograms were reported negative except for the retention. No evidence of malignancy was found. The gastric contents showed normal chemistry. Duodenal drainage has been carried out a number of times, magnesium sulfate, diluted hydrochloric acid and tincture of *Cardus marianus* being used as stimulants. No B bile has been obtained on any occasion. Flushings of the biliary system with various choleagogues gave no relief. Numerous preparations used to relieve the nausea had no apparent effect. The red count was 5,230,000, white count 8,200, hemoglobin 80 per cent. There is a slight dehydration present. A Hinton test was reported negative. A specimen of blood was reported negative for typhoid and paratyphoid and positive for undulant fever in a titer of 1:80. At the present time I am giving her injections of undulant fever vaccine at four day intervals. As she gets a fairly severe reaction locally, I have not increased the initial dose of 0.2 cc. In view of the failure to obtain B bile, I am continuing to carry out a duodenal drainage once a week. In addition she is getting sulfanilamide 5 grains every four hours. She has no fever at the present time and no night sweats. Her headache is unchanged and quite severe; she still has severe backaches, and the epigastric distress remains, with the anorexia. None of the usual analgesics relieve the headache. Any suggestions as to further laboratory work or therapeutic measures would be greatly appreciated. Economic conditions are such that I would not want to advocate expensive procedures unless they were clearly indicated.

M.D., New Hampshire.

ANSWER.—The information given is not sufficient to exclude numerous diseases; consequently, many additional laboratory procedures and continued observation may be necessary to arrive at a clinical diagnosis. The symptoms and observations described are compatible with brucellosis (undulant fever) but this diagnosis cannot be considered as definitely established.

Undulant fever, as the term implies, is characterized by fever of various types, degrees and duration with a tendency to relapse. This is one of the most constant clinical characteristics of the disease. The patient was apparently known to have had only one febrile episode and this of short duration. This would be a somewhat unusual course in undulant fever. It has been noted that patients with brucellosis are frequently unaware of a considerable degree of fever, and unless the temperature is taken daily at regular intervals both the patient and the family may not suspect that it is elevated. A temperature chart may be of great diagnostic value and if, under these circumstances, the patient's temperature has been and continues to be normal, the significance of the 1:80 agglutination titer is questionable. Such a titer may result from a past infection which is inactive at present. In the event of an active untreated infection the titer is ordinarily found to increase when the agglutination test is repeated at intervals of several weeks. Vaccine and sulfanilamide therapy may affect both the fever and the agglutination titer, and this should be taken into consideration in the interpretation of the findings. The white and differential blood counts may be helpful. The typical blood picture in undulant fever in the absence of secondary infection is that of a leukopenia with a relative lymphocytosis. The spleen is often enlarged but not always palpable. The intradermal test for undulant fever has definite limitations in the diagnosis of an active infection. The skin of practically all persons who have had brucellosis remains permanently allergic to the antigen used in the standard intradermal test. When this allergic response is absent, that is, when the test is negative, it is usually considered strong but not conclusive evidence that the patient has never had a *Brucella* infection. In the presence of an active brucellosis, the intradermal test is almost always positive and the opsonocytophagic test is negative, whereas when both the intradermal test and the opsonocytophagic test are positive the infection is considered inactive and may, in fact, have completely subsided years before. Investigators, however, do not all agree as to the reliability and interpretation of the opsonocytophagic index, which incidentally is the quantitative determination of the patient's neutrophilic leukocytes to phagocytize *Brucella* organisms. Furthermore this is not a simple determination, and some experience with the method is usually required. The diagnosis of an active *Brucella* infection may, indeed, be difficult and can usually be made with absolute certainty only when cultures from the blood, stool or urine yield *Brucella* organisms. In rare instances the organism has been found in the bile. Unfortunately negative cultures have little significance, since *Brucella* organisms are not always found in persons proved by their subsequent course to have had an active brucellosis at the time repeated cultures were made. Further details of these tests can be found in Huddelson, I. F.: *Brucellosis in Man and Animals*, New York, Oxford University Press, 1939.

In view of the fact that the patient may have had influenza six weeks ago and has since then been afebrile, certain non-infectious diseases may merit further consideration. No mention is made of a cholecystogram. Unless the jaundice is severe or the patient is unable to swallow the dye, this might be of value. The history and findings as given could be those of a malignant growth, particularly of the digestive tract, and more specifically of a cancer of the pancreas or the stomach. Carcinoma of the pancreas is frequently difficult to diagnose clinically even when the best laboratory facilities are available. It is sometimes suspected in patients with some degree of icterus which persists and becomes progressively worse, particularly when associated with a severe backache and a suggestive epigastric mass in the absence of a demonstrable intrinsic lesion of the stomach or the duodenum. This impression is not infrequently confirmed at operation or necropsy. The frequent association of cholelithiasis and carcinoma of the pancreas may confuse the clinical picture.

It has often been emphasized that gastric carcinoma may be asymptomatic until a late stage, even when numerous metastases have already occurred. It has also been observed that a small, hardly detectable carcinoma of the stomach may give rise to widespread metastases and that, in fact, the first complaints of a patient may be due to distant metastases. An early or small gastric carcinoma may barely arouse the suspicion of even the most expert roentgenologist, and not uncommonly it is necessary to repeat the roentgenologic examinations one or more times to arrive at a definite opinion.

Since carcinoma of the stomach is one of the most common cancers, it is always well to keep this possibility in mind, particularly in persons over 40 years of age who complain of digestive disturbances of only a few months' duration. The

initial symptoms are often vague and may not direct attention to the stomach primarily. Stools collected while the patient is on a meat-free diet and in the absence of bleeding from the upper respiratory tract usually, but not always, give a positive test for occult blood. When hemorrhoids are present, as is frequently the case in elderly people, it is preferable to test material from the center of a fresh stool. The persistent presence of occult blood in the stool is not diagnostic of any particular condition but demands an explanation. In elderly people it is always suggestive of a gastrointestinal cancer and, unless the bleeding can be satisfactorily explained, a thorough proctoscopic examination is indicated. It should be noted that the passage of a stomach or duodenal tube may in itself result in occult blood in the stool for some days. The presence of free acid in the gastric contents does not exclude the possibility of gastric carcinoma. In some series free acid has been found in almost 50 per cent of the cases of carcinoma of the stomach at the time of diagnosis.

In the event of a malignant obstruction of the biliary tract, jaundice usually becomes progressively more pronounced. In obstruction due to cholelithiasis, jaundice is more apt to fluctuate or subside. This is sometimes best followed by serum bilirubin determinations at intervals of a week or so, and when this method is not available the icterus index can be used.

When free acid is present in the stomach contents of a patient with gastric retention, and chlorides and fluid are lost by vomiting or aspiration, alkalosis may result. The carbon dioxide capacity of the blood is then increased and the serum chloride is decreased. Headache is a common symptom in alkalosis and usually does not improve unless specific therapy is instituted. When parenteral fluids and saline solution are given, the symptoms of alkalosis almost invariably subside and not infrequently the improvement is spectacular.

Cardiorenal vascular disease accompanied by nitrogen retention may also cause severe persistent headaches refractory to almost any form of therapy. However, the patient's blood pressure seems to exclude this possibility, and furthermore the urinalysis would probably have given some indication of this. The patient's blood urea nitrogen level is apt to be elevated in view of the dehydration, and under these circumstances it is often difficult if not impossible to estimate the renal function unless sufficient fluid is given to do a urea clearance test. The fluids would, of course, have to be given parenterally to this patient.

Unfortunately the procedures which may be necessary to arrive at a diagnosis are not all simple. Therapeutic measures must of necessity be supportive until the primary pathologic condition can be recognized. The question arises as to whether the nausea might not be aggravated by sulfanilamide. In view of the dehydration and inability to take sufficient fluids by mouth, parenteral fluids are strongly indicated.

DIAGNOSIS AND TREATMENT OF MÉNIÈRE'S SYNDROME

To the Editor:—A patient has what is considered Ménière's syndrome. Spinal manometry and ophthalmoscopy reveal nothing of significance. The attacks of vertigo, nausea and vomiting are disabling, especially since the subject tends to be somewhat neurotic. 1. Does impairment of hearing have to be present in order to consider it a true Ménière's syndrome? There is no impairment of hearing. 2. The recent onset precludes consideration of operative intervention at this time. Has any confirmation been obtained regarding the use of electrolytes, orally, for the control of the dizzy spells? Is the method worth trying? If so, what salts are used? Dosage and other pertinent material is requested. 3. Have statistics been published on spontaneous recovery in this affliction or an recovery after various methods of treatment? Isidore I. Weiss, M.D., Stockton, Calif.

ANSWER.—1. Ménière's syndrome is defined as attacks of vertigo of otitic origin associated with tinnitus and deafness. However, it is possible for the tinnitus and deafness to be absent, at least in the early stages.

2. The medical treatment of Ménière's syndrome is based on (a) removal of etiologic factors such as chronic middle ear suppuration, foci of infection or allergic factors; (b) symptomatic treatment based on the assumption that the periodic attacks of vertigo are due to an edema or increase in intralabyrinthine fluid pressure: restriction of the intake of sodium, especially in the form of sodium chloride, restriction of the fluid intake to 1,000 cc. a day and the administration of potassium chloride or ammonium chloride to stimulate the excretion of sodium in the urine and thus to reduce a tendency for fluid retention in the tissues, since the sodium ion seems to be an important factor in fluid retention. (Dosage: ammonium chloride 3 Gm. with each meal in capsules, 6 capsules, each containing $7\frac{1}{2}$ grains [0.5 Gm.], taken during the meal, three days on, two days off. Or potassium chloride, 2 teaspoons, 25 per cent solu-

tion, three times a day. All of these medical measures are worth trying. Not all of them give results in every case.

3. It is a frequently recorded fact that Ménière's disease tends to be self limited and after a variable length of time, months or years, the attacks may cease spontaneously. In some cases the hearing impairment becomes stationary and permanent; in others the hearing improves as the attacks cease. Because of this tendency to spontaneous recovery, operative intervention should be reserved for only the most stubborn and disabling cases of vertigo, and the results of treatment must be interpreted cautiously.

COTTONSEED SENSITIVITY

To the Editor:—Would you please inform me whether a person found sensitive to cottonseed is to avoid contact with all cotton and finished products, such as bed sheets, pillow cases, dresses and underwear or do the different processes through which cotton passes from the crude to the finished forms destroy the allergic property of the cottonseed embryo?

Jacob Reicher, M.D., Brooklyn.

ANSWER.—The cottonseed allergen is not present in the pure cotton fiber. The latter is almost totally insoluble in aqueous mediums. If there are any instances of allergy to such cotton products as bed sheets, pillow cases and underwear they are extremely rare and, when suspected, are probably due not to the cotton itself but to dyes and other finishing products. Of course, when the cotton contains some of the seed particles, such as is found in cotton linters, then the material does have the cottonseed allergen. When raw cotton ages, the dust formed contains a new allergen which is ordinarily called the house dust allergen. People become sensitive to this dust, but this material antigenically has no relation to the cottonseed.

OFFENSIVE FLATUS

To the Editor:—A healthy white man aged 41 complains of gas which is expelled with an offensive odor. This is the only complaint. It has been present for about two years. Constipation is avoided by taking heavy liquid petrolatum daily. All habits are excellent. The patient does not smoke. He says he wants to live a long time and live comfortably physically. I am unable to relieve this condition. Physical examination reveals no abnormalities. The man eats a balanced diet. What is causing this condition? What diet do you suggest? What medication do you advise? This information is crude, but there is no other information to give. M.D., South Carolina.

ANSWER.—The passage of unusual amounts of foul smelling flatus suggests a dysfunction of the digestive tract which permits unusual amounts of poorly digested or assimilated foods to reach the colon. Intelligent treatment requires a more complete diagnosis. The examination of fecal specimens is required, and this is a procedure most frequently neglected. A highly acid stool containing undigested carbohydrates would indicate a fermentative process and the need for a diet low in carbohydrates. Putrefaction must also be excluded. In any event the use of liquid petrolatum should be stopped, organic causes of the constipation excluded and a normal intestinal function restored with a diet rich in cooked fruits and vegetables. In some persons the habitual use of liquid petrolatum alone may cause considerable disturbance of intestinal digestion and absorption, especially of vitamins, and give rise to a condition such as that described.

ointment BASE FOR SULFATHIAZOLE

To the Editor:—In the Journal, Jan. 25, 1941, page 536, a formula is given for sulfanilamide ointment. Could sulfathiazole be used instead of sulfanilamide in this formula? If not, is there a formula in which sulfathiazole can be used? Ellsworth Wilson, M.D., Highland, Ill.

ANSWER.—Sulfathiazole cannot be incorporated easily in the ointment base mentioned. Cod liver oil or hydrous wool fat base seem to be more satisfactory for incorporating sulfathiazole.

THE EDUCATION OF A DERMATOLOGIST

CHAIRMAN'S ADDRESS

J. G. HOPKINS, M.D.
NEW YORK

The increasing demand by recent graduates in medicine for advanced training in various specialties has made necessary the current effort to develop the facilities for such education. Our graduate departments are still in their formative stage. Methods and organization vary widely in different institutions. Changes will doubtless take place as these are tested by experience. It may be of interest, therefore, to consider at this time the procedure to be followed and the facilities necessary for the education of specialists in dermatology.

METHODS OF TRAINING

The object is to develop in students an understanding of disease and skill in its management rather than to furnish them with information. This makes the choice of method important. A man must build his understanding by observation and reasoning and develop skills by practice. Neither can be set up in his mind from prefabricated units. The belief that education should begin with individual phenomena and generalizations arrived at by correlating things observed is as old as Socrates. It has been called the inductive method to distinguish it from all which teach the student facts and theories by which he may explain his observations or rules by which he may work.

The essence of inductive education is in the system of teaching anatomy developed by Mall. The student was given a part and made to dissect. Only after he had found the fascia, the muscles, the nerves and the blood vessels was he to read about them. No lectures were given, only individual discussions with the demonstrator in the dissecting room. Osler made his students clinical clerks. They took histories, made examinations and drew their own conclusions before discussing cases with their instructors. Richard Cabot taught about cases, not about diseases.

Forty or fifty years ago these ideas revolutionized medical teaching. We still avow our belief in them, but adherence to the principle of inductive education presents practical difficulties. For one, there is such a terrific variety of problems which may suddenly confront a practitioner that it is impossible to have experience with them all during the student years. The

conscientious teacher fears what his pupil might do in some predicament that had never been explained to him.

Does the memorizing of symptoms, signs and treatment help? You have all been taught the antidotes for phosphorus, how to reduce a subcoracoid dislocation and how to manage a face presentation. How many remember? In an emergency, would you not have to depend on some general principles derived from cases which you had managed or help to manage? How often the instructor who has spent hours drilling a subject into the student's head is surprised to find on later examination only faint and distorted traces of it all. Yet this is the normal fate of information that is not rooted in experience.

As science and practice have progressed, the undergraduate curriculum has become more and more crowded. In the laboratory most so-called experiments follow explicit directions to a predicted conclusion. In the clinic demonstration is often substituted for practice. In all departments a variety of diseases, techniques and theories are discussed in rapid sequence, and the student is forced by ordeal of examination to load his memory with information that he can never retain.

I suspect that our present medical curriculum would benefit from a radical débridement. If we could eliminate all the things that students will forget within two years of graduation we would reduce the factual material by at least one half. Should we do so our graduates would write deplorable examinations but they might make better doctors.

However, that is all an intricate problem on which I would not seem to pass cursory judgment. I say all this because I believe that in organizing graduate training we have an opportunity to develop truly inductive education. We can start unhampered by fixed ideas of details that must be covered. To do so would be in accord with our best traditions, for with all our faults we dermatologists have long had the virtue of objectivity. Our favorite occupation at meetings is examining interesting cases, and our journals are filled largely with case reports.

However, if we are to use inductive methods, we must realize that we cannot teach as many men as many things in as short a time as we might by a didactic system. We must abandon the hope of covering our whole subject or of turning out a finished product. We can, however, train our students to observe and to reason, to evaluate their own experience and to comprehend the developments of science and use them in the solution of their problems. These matters are more important than their present proficiency. They have an expectancy of life of perhaps thirty-five years. In that time medicine will advance. Few of the technical methods, only some of the concepts or even terminology that we teach them today will survive.

From the Department of Dermatology of the Vanderbilt Clinic and the Columbia University College of Physicians and Surgeons.
Read before the Section on Dermatology and Syphilology at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 4, 1941.

PROGRAM OF TRAINING

In order to derive ideas of disease from observation of cases, the student should spend the major part of his training period in the clinic and wards. He should examine and treat his own patients and follow them through the course of their illness. He should attend consultations about them in other departments. His work must, of course be controlled by an instructor, both for his own good and for the protection of the patient, but demonstration and discussion should come only after he has himself worked out a problem as best he can.

The student should serve successfully in each department of the clinic so as to gain experience with representative types of disease and different technics of treatment. His course should include a term of residence in a hospital, for there is no adequate substitute for the experience of living with patients and with colleagues working in related fields. The running time of this clinical experience requires careful planning, but the schedule should not be rigid. It should be adjusted to the interests and abilities of the individual student.

Laboratory diagnosis should be learned by examination of specimens from patients whose clinical course he can observe. Systematic laboratory courses seem necessary in histopathology and perhaps in mycology and other subjects. Such courses will, however, mean far more if used to systematize ideas derived from previous study of his own cases.

Physical therapy again is best learned by actually using the apparatus. Once a student has mastered the technics of the clinic where he works, a study of other systems will have meaning, and a discussion of physical principles and of the structure of apparatus will answer questions that have already arisen in his mind. The same applies to other therapeutic technics.

The basic sciences present a difficult problem. It is obviously desirable that the student should understand chemistry and physics, physiology, pathology and microbiology as related to dermatology; but, if we are to use inductive methods, we cannot cover all these subjects, or any one of them completely, within three years. In this quandary we may find a solution in the practice of other graduate departments. A candidate for the doctorate of philosophy chooses his major subject and elects one, or perhaps two, minor subjects which should aid his understanding of the first. Graduate training in many departments of medicine has been similarly organized. I would have each student of dermatology elect one science and spend at least six months (or half time for a year) in a laboratory, not taking courses but working. At first he may do well to assist some experienced investigator in a problem unrelated to dermatology in order to lay ground work and acquire technic, but sooner or later he should attack a dermatologic problem. As in the clinic, work must be supervised and guided, but it should be planned and executed by the student.

In this he may make no great contribution to science, but he will learn to outline an experiment that will answer a question, to use precise technic and to evaluate results. These matters are common to all sciences and should govern his work in the clinic. The student will also gain understanding of the processes which he studies, so that he can think of his clinical problems in terms of cell permeability or of lipid metabolism or of specific sensitization—whatever may be his particular

field. This ability and the intangible effect of informal and intimate association with men of the laboratory will influence all his future work.

I would emphasize the value of such training for the development of the science of dermatology. If there were coming into our group young men trained in pathology, others in some branch of chemistry or physiology and still others trained in microbiology, we would see progress. Each would have ideas and methods with which to attack the problems that confront him in the clinic. Each would be able to discuss questions and to teach students from some special and illuminating point of view.

If we undertake training of this type, no time will be left for short courses in other branches of science. Does that mean our student can learn nothing of the other sciences that are necessary for his clinical understanding? I submit that he should gain a truer comprehension of these sciences by thorough work in one than by short courses in all. If what he needs cannot be derived from observation in the laboratory, much can be learned in the clinic. We should be able to teach as he faces his patients by discussing the physical and chemical processes that are going on before his eyes. He could then derive his ideas of biology from observation of clinical phenomena and such ideas would have reality.

A program such as I have outlined may be embroidered with clinics, demonstrations, lectures and seminars if one remembers that they are just embroidery and that the basic fabric is clinical and laboratory work. The more active participation by the student such exercises demand and the more they stem from the work he is doing, the better. They may be useful in stimulating interest. They often point out topics that should be studied. They may be used to assemble and evaluate material that is scattered in the literature. The student should not, however, devote too much time to watching others work or listening to what they have to say. As Mall¹ remarked, "The very name 'student' tells what the person so named should be doing."

FACILITIES FOR TRAINING

Training of the type just discussed requires more extensive equipment and makes greater demands on the time, interest and ability of the staff than does a more formal type of instruction.

1. *An Outpatient Department.*—This should be arranged in sections so that patients requiring special forms of treatment, such as radiotherapy, chemotherapy or minor surgery, or special diagnostic procedures, such as allergic studies, and also those presenting some problem under investigation may be grouped together. As dermatologists now bear the main responsibility for the care of syphilis, a special section should be equipped for this purpose. The clinic should also have diagnostic laboratories for histopathology, mycology and bacteriology and possibly for other fields. It should be equipped for radiotherapy, actinotherapy, minor surgery and other forms of treatment of special importance to the dermatologist. The laboratories and treatment rooms should be grouped in the clinic so that the student may use them for his own cases and so correlate this work with his clinical observation. The clientele

1. Mall, Franklin P.: *The Anatomical Course and Laboratory of the Johns Hopkins University*, Bull. Johns Hopkins Hosp. 7: 85 (May-June) 1896.

of the clinic must be large enough to include examples of the rarer dermatoses.

2. *A Ward Service.*—This should be large enough and sufficiently endowed to provide the prolonged hospitalization required for severe chronic dermatoses. It should be designed, equipped and staffed especially for its purpose. The conventional hospital ward is ill adapted for the care of our patients, many of whom are ambulant and many of whom require isolation. Few nurses or orderlies know anything about their special care. Actinotherapy, balneotherapy, fever therapy and dust-free rooms are among the many special requirements.

3. *Research Laboratories.*—It is important for the education of both students and staff that research be conducted within the department. Rooms equipped for chemical, physiologic, pathologic and microbiologic work with easy access to clinic and wards should be provided.

4. *Teaching Space.*—Conference and demonstration rooms, a small department library, offices for the staff and desks in the laboratories or elsewhere for each student should be provided, and perhaps even a lecture room for rare occasions.

5. *Staff.*—The clinical staff should include men specially interested in different phases of dermatology. They should have time for teaching and research as well as for the care of their patients. Whether they are "full time" or "part time" is not the chief criterion of their effectiveness, but at least a group of junior men on adequate salaries devoting full time to the institution seems essential. A similar senior staff would be desirable.

The laboratory staff should include at least a pathologist, a chemist, a physiologist and a mycologist. To obtain such a staff means finding not only the men but salaries, technicians, equipment and supplies. Their selection would be determined by the main lines of investigation which were planned. They would be most effective if chosen to do correlated work on some general problem, for example avitaminosis.

6. *Fellowships and Residencies.*—These should be provided for the students. The problem of support becomes more difficult as a man becomes older, and few can carry on a long period of graduate study if compelled to pay their expenses.

The department should be a part of a medical school and hospital. Its clinic, its laboratory and its library should provide only those facilities of peculiar importance to dermatology.

THE OPPORTUNITY

Perhaps I have said too much about methods and equipment. In all education the essential thing is the teacher. We have among us those who, by their own force and ability, have done outstanding work with inadequate facilities and scant financial support. They deserve the greater credit for succeeding under these handicaps.

What I would emphasize is the desirability of providing our teachers with the means for proper graduate education. These are essential if they are to develop future teachers and practitioners who will bring to patients with disease of the skin the full benefits made available by the advance of science.

An organization such as I have tried to outline is not to be found in this country. Many schools, otherwise

lavishly equipped, make practically no provision for dermatology. Few have sufficient ward space and none have adequate laboratories. Yet the clinics of Breslau, Zurich and Strasbourg were, until recent upheavals, developed much along these lines, and Berlin, Vienna, Paris and other European centers had clinical facilities more extensive than those I have suggested. Why has so little been done here?

Fortunately many departments of internal medicine and of surgery and some of pediatrics are almost ideal in their organization and equipment. There are excellent institutes for neurology, psychiatry, ophthalmology and urology. The needs of dermatology and the opportunity it offers for advancing the science of medicine seem almost unrecognized by our organizers of medical education.

This is not the place to discuss the contributions of dermatology to medicine, but I would remind you that dermatology has led the way in recognition of the varied clinical response to infection with the tubercle bacillus, that sarcoidosis was familiar to the dermatologist before the internist was aware of its existence, and that the same may be said of lymphogranuloma venereum and coccidiomycosis. Studies on sensitization of the skin have contributed much to our knowledge of allergy. The modern treatment of syphilis and consequent control of that disease have been developed largely by dermatologists.

No field should offer greater attraction to those who wish to carry on investigation. There are many well classified dermatoses the etiology of which is quite unknown—almost as many as there are internal diseases. In few lesions can the mechanisms of disease be so directly studied as in those of the body surface which can be closely and continuously observed, tested as to their response to various stimuli and repeatedly sampled for chemical or microscopic study.

In an address before the Congress on Medical Education and Licensure, Alan Gregg² listed and discussed "special opportunities for development in medicine in the decade now before us," among them dermatology. May I quote from his remarks?

In many American medical schools the budgetary support for dermatology is farcical. . . . Is it in any sense wise . . . to deny a considerable number of beds and the contributions of histology, physiology, biochemistry, pathology, bacteriology, psychiatry and internal medicine to the dermatologists? The usual skimping of scientific resources and collaboration for the dermatologists presents the classic picture of deliberate neglect in that the chief losers are probably not the dermatologists but medicine as a whole. It is exactly from neglected fields that we may expect our most significant advances.

Why We Need Water.—Practically all the body materials except skin, cartilage, bone and fat will dissolve in water, and every kind of tissue contains much of it—from bone, which is about one-third water, to a fluid tissue like blood about four fifths of which consists of water. In every cell of the body the materials of which it is made are present in watery solution, while about 10 pounds of water are circulating constantly to all parts of the body to carry soluble nourishment to the cells and soluble waste products away from them.—Bogert, L. Jean, and Porter, Mame T.: *Dietetics Simplified*, New York, Macmillan Company, 1940.

PATIENTS' ATTITUDES AND BEHAVIOR IN WARD ROUND TEACHING

JOHN ROMANO, M.D.

BOSTON

Bedside teaching is an established procedure in medical education. Its value as a teaching method and the advantages and disadvantages to the instructor and student have been considered by others. The patients' reactions to this procedure, on the other hand, have received little attention. There have been numerous essays which have considered the patient-physician relationship and the need for interpretation of personality structure with expression of sympathy and tact at the bedside. However, these have not been based on direct study of patients' reactions and are, for the most part, points of view and appeals for sympathetic attitudes.

In order to obtain more objective data, an investigation was undertaken to study patients' reactions and behavior during ward round teaching. Specific attempts were made to discover whether the experience is traumatic, to gain further insight into patients' reactions to their illnesses and to learn how the procedure might be utilized as psychotherapy.

METHODS OF STUDY

Ward Rounds.—One hundred unselected patients in the medical service of the Peter Bent Brigham Hospital were studied before, during and after Saturday morning teaching rounds. These rounds consist of the presentation of 1 or 2 patients from each of the four medical wards to a group of from fifty to seventy persons comprised of members of the hospital staff, visiting physicians, students and nurses. The patient is placed in his bed in the center of the ward with the case records, laboratory sheets, charts, roentgenograms and other laboratory preparations on adjoining tables and screens. Usually a patient has had to wait from a few minutes to an hour before rounds reach his ward. As the group enters the ward and disperses itself around the bed, the presiding physician speaks to the patient and introduces himself if the patient does not already know him. After the significant data have been presented by the house officer, the patient may be interrogated and examined by the various staff members. Various details of the history, physical examination or laboratory data may be reviewed more specifically with suitable objective preparations. Following this, there is a discussion of the various diagnostic, therapeutic and prognostic aspects of the problem. Occasionally guest clinicians and investigators are present to discuss problems in which they have special interest. In most instances patients remain for the complete discussion period. The total period of presentation of one patient varies from thirty to ninety minutes.

This teaching procedure was chosen in preference to the daily, more informal ward rounds, since the former is more uniform in the preparation, observation and examination of patients, in the manner in which it is conducted and in the staff direction. It was assumed that if untoward results were to occur they would occur more frequently in the former procedure, as the formal, more public experience is associated with more anxiety.

Preparation of Patient.—All patients who were presented were seen by the senior house officer of the ward the preceding afternoon or evening. Each patient was told that he was to be presented before a large group of physicians, that he was chosen because his problem presented certain difficulties which would be better understood and treated after general discussion, that he would be examined or interrogated concerning his illness and that the conference would last approximately one-half hour.

Before presentation, each patient was studied for an evaluation of his personality structure and the emotional significance of the illness to him. In addition, pulse, respiration and blood pressure were determined.

Examination During Presentation.—During the presentation the patient was observed for changes in facial expression, blushing, pallor, sweating, restlessness, crying and laughter. Care was taken to observe the patient's reaction to the approach of the group to the bedside, the recounting of the history, the examination, the questioning and the discussion or absence of discussion. The influence of any ambiguous or untactful remark concerning the patient, his illness or experimental data allied to the latter was noted particularly. Pulse, respiration and blood pressure were determined at the conclusion of the presentation.

Examination After Presentation.—The patient was interviewed from one to three hours after the presentation. Objective evidences of anxiety were noted. When possible, a spontaneous discussion of the patient's reactions to the teaching procedure was obtained. This was supplemented by questions related to various phases of the procedure. Many patients were asked to define certain medical terms and abbreviations used at the bedside. Interviews were also held with ward nurses, fellow patients and relatives in order to supplement and objectify the patient's responses.

With the exception of 4 girls aged 9 to 12 years and 1 boy aged 13, the patients were adult. The disorders were those observed in a general hospital medical service and thus included infectious, deficiency, metabolic, neoplastic, degenerative and psychogenic processes in varying degrees of severity.

By means of the psychiatric examination preceding the presentation, the patients were classified as having (a) little anxiety associated with their physical disease (29 men, 30 women), (b) considerable anxiety associated with their physical disease (9 men, 16 women), (c) predominantly neurotic symptoms with no demonstrable disease (2 women) and (d) confusion or fluctuation of the level of awareness due to various toxic or allied factors with varying degrees of anxiety (11 men, 3 women).

RESULTS

No severe emotional trauma was observed. In instances in which patients were tense or anxious, the reactions were mild and in no way resembled panic reactions. On the contrary, the attitudes and behavior of these patients revealed considerable insight into the positive value of ward round teaching. In the following, the attitudes and behavior of patients will be discussed as they were observed during the various phases of the teaching exercise.

Behavior and Attitude Before Presentation.—Only 4 patients disapproved of the preliminary explanation. By each of these the explanation was not completely understood. A 27 year old housewife of limited intel-

lectual endowment, experiencing considerable anxiety with erythema nodosum, complained that she had not understood the explanation and that she had been perplexed by the ward rounds. A second patient, an elderly Italian housewife who understood little English, worried over what the doctor had told her before the exercise. The remaining 2 patients were confused before and during the presentation. In these 2, the fluctuation of the level of awareness was apparent. Significant, from a positive point of view, was the grateful appreciation of most of the patients for this preliminary explanation. Not unusual was the expression of a woman aged 64 with facial erysipelas: "Seems to me you doctors could make us feel better if you spoke our language and told us some of the things that are happening to us."

In this phase before presentation, the significant untoward reactions were those of varying degrees of anticipatory anxiety. Twenty-four patients expressed themselves as feeling uneasy, tense, restless, anxious for it to be over or wondering what was to take place. Of these 24 patients, 12 had been considered to be experiencing considerable anxiety in their illness, 7 were confused and 2 were neurotic personalities without physical disease.

Behavior and Attitude During Presentation.—The anticipatory anxiety reached its peak immediately before and during the entrance of the group to the ward. Those patients who experienced anxiety most intensely were those previously noted. They comprised less than one fourth of the total number. In 16 there were objective evidences of tension characterized by blushing, motor restlessness, tossing of the head on the pillow, sighing respirations and picking at the bed linen. In addition to the remarks describing restlessness and uneasiness, the patients complained of "funny feelings in the stomach," "abdominal rumbling," "as if I had to pass water," "my heart beat fast and turned over." Only the 2 neurotic women showed significant changes in pulse and blood pressure. The anxiety of these patients was greatest as the group approached the bedside, decreasing after that. The following remarks illustrate the "let-down." A shy, sensitive youth-aged 17 convalescing from pneumonia stated: "I was pretty nervous before they came in, wondering what was to happen, but after they came in and the doctors began to tell them about my case, I felt much better." A young housewife with respiratory alkalosis and tetany associated with her anxiety stated: "My heart kind of went funny, my hands perspired and that funny feeling in my face and hands was coming on before they came in. After they came in it wasn't as bad as I thought it was going to be."

Thirteen patients were distressed by the recitation of the history. The following factors were of most importance: When historical data were presented which were unfamiliar to the patient, they caused considerable surprise and concern. This was illustrated by a young man who had experienced amblyopia and convulsions in the course of hypertensive encephalopathy. It was during the recitation of the history that he became aware for the first time that he had had seizures. This surprised and alarmed him, and he asked why he had not been told before and what was the significance of the seizures.

The recitation of data related to past or present personality difficulties led to resentment, anger and

humiliation. A young Greek-American housewife with endemic malaria enjoyed the presentation and discussion. However, she resented and was humiliated by the inclusion in the history of an attempt at suicide nine years before. "I felt as if my soul was exposed, and the fact that I did try to commit suicide I wish he hadn't said before all those people."

Social data, especially if they concerned prestige or security factors, provoked resentment. An elderly woman with tuberculous peritonitis became upset when it was stated that she was a fortune teller. She had had two trichobezoars removed from her stomach in the past, and she was relieved when the term "trichobezoar" was used in preference to "hair ball." On inquiry it was found that the patient did not mind being known as a fortune teller, but she feared that the relief authorities would curtail her allowance if they believed that she had other sources of income.

In the following, the use of a descriptive phrase acted as a trigger which allowed the patient to express considerable resentment which had previously been concealed. An educated, formerly successful business man who was addicted to alcohol and had multiple nutritional deficiencies was most disturbed when it was mentioned that the pain in his feet was thought to be due to poorly fitting secondhand shoes. "The only thing that bothered me at all was the mention of the secondhand shoes. That sort of wounded my dignity. Why couldn't they have said on old pair of shoes?"

From a positive point of view, most of the patients received considerable satisfaction from hearing the history. Many stated that they had heard it often enough so that they were on the alert for changes, and occasionally they would take pride in correcting the house officer concerning this or that point. Many expressed frankly that it was comforting to know that the doctors had taken such pains to learn all about them.

Seven patients were annoyed by physical examinations during the procedure. Two factors seemed to be of considerable significance. One was the sensitivity and embarrassment of patients to being disrobed and examined before a group. A sensitive obese girl thought every one was looking at her fat legs. A slightly confused myxedematous woman stated that too many had felt of her hair and skin. The second factor resulted from confusion following examinations which drew attention away from the principal complaint to a new anatomic site. This new and usually misunderstood emphasis caused considerable distress. A boy aged 13 with diabetes and nephrosis asked: "I wondered why they examined my heart so long; I haven't got heart disease, too, have I?" When attention was directed to a hitherto unnoticed adenomatous thyroid nodule in an elderly Negro suffering from an abdominal complaint, it perplexed him and led him to say: "My trouble is in my stomach. I can't see why they kept on feeling my neck and talking about operations."

Three patients were disturbed by the presence of charts, diagrams and roentgenograms. In each instance, this occurred in anxious patients who had been perplexed as to what the data signified.

The patients were untroubled by the infrequent group laughter which took place during ward rounds. Many patients laughed with the group and felt more at ease after it. A prim housewife laughed with the group when her spleen, once enlarged, was no longer palpable. Later, she appeared pleased with her description: "It's

not a palpable but an elusive spleen." No ideas of reference or undue sensitivity arising from the laughter were noted.

Behavior and Attitude During Discussion.—Of the 69 patients who remained for discussion, 11 would have preferred to have been removed from the ward. The reasons given for preferring to leave were those related to physical discomfort (pain, fatigue, hunger), those related to anxiety and those related to indifference concerning the medical discussion.

Thirty-one patients were removed before discussion. Fifteen were removed for reasons of physical disease, 12 because of anxiety and 4 for experimental purposes of comparison. Sixteen of the 31 patients would have preferred to remain for the complete discussion. This preference was based on the beliefs that they did not want to miss anything concerning themselves and that they gained reassurance from the group discussion. This preference was particularly true if patients had been presented previously or if they had seen other presentations. In these instances considerable anxiety was expressed when the patients were removed. As one patient stated: "This happened once before and I stayed through it. This made me wonder why I couldn't stay and whether my condition was getting worse."

Over half the patients stated that they understood the essential substance of the discussion. However, a much smaller number gave objective evidences of such understanding. The fact remains that discussions dealing with the care of diabetes, heart disease, hypertension, arthritis, and peptic ulcer were of such a nature that they served to educate the patient in the care of his disease.

All patients were pleased by the personal interest of the staff. The presence of the nurse at the bedside, a reassuring word and the calling of the patient by name did considerable to allay tension and anxiety. One elderly scorbutic patient, impressed with the friendly interest of the presiding physician, said: "It made me feel important, too—almost as important as these damn red splotches on my skin."

Divergent opinions of the discussants played no significant role in distressing the patients. Actually, the interchange of staff opinion was a source of reassurance to most patients, as they believed their problems were studied more thoroughly.

Sixteen patients believed that the discussion lasted too long; five were of the opinion that it was too short. Some of the expressions supporting the latter opinion demonstrated the prestige value and the intensity of emotional concern associated with the illness.

An elderly patient with postural hypotension asked if it were true that he had a rare and interesting disease. When told his condition was relatively uncommon and that a number of the staff were interested in the condition, he asked somewhat indignantly "Then, for heaven's sake, why didn't they talk about it longer than ten minutes? Why, twenty years ago I was operated on for hemorrhoids at the — — — hospital and they talked about my case for half an hour!" A frequently hospitalized elderly woman with angina announced to her bed neighbors that this was the morning she was to be the "duchess of the ward."

A middle-aged man, considerably concerned about a severe headache which had remained undiagnosed,

believed the discussion was altogether too short, since no one seemed to be able to throw any light on his problem.

Vocabulary.—Fifty patients were asked to define sixty medical terms and abbreviations used frequently in bedside conferences. These terms included "acid-fast," "CA.," "lues," "neoplasm," "mitosis," "Koch's bacillus," "P. A.," "G. C.," "ALC.," "EKG," "Wassermann," "growth," "tumor," "shock," "stroke," "neurotic," "nervous breakdown" and "prognosis."

No patient understood the terms "mitosis," "neoplasm," "metaplasia," or "metastasis"; 2 knew what "CA." meant; 3 understood "malignancy" and "carcinoma"; the majority interpreted "tumor," "growth" and "new growth" as "cancer," or as something growing somewhere, usually in the stomach. "Koch's bacillus" was totally unfamiliar. "Acid-fast" meant "contagious" or "concerning a germ" to one patient. "TB" was known by the majority of the patients. "Serology," "specific infection," "P. I. D.," "Hinton," "complement fixation," "Neisserian" and "spirochetal" were unfamiliar. Only 2 patients understood "lues" correctly; 8 understood "G. C." and 10 understood "Wassermann." Ten patients knew "leukemia"; 5 interpreted "lymphoma" and "Hodgkins" as "gland swellings"; 4 were familiar with "P. A." The terms "hypertension," "coronary" and "angina" were interpreted as dealing with the heart by 11 patients. "Shock," "stroke" and "paralysis" were used interchangeably. "Neurotic" was usually interpreted as "being off," "nuts" or "due to imagination," while "nervous breakdown" was attributed to overwork. "Degenerative" was usually interpreted in the moral sense of an antisocial, perverse personality, rather than a destructive tissue change. "Prognosis" was vaguely familiar to many, defined correctly by 1 and defined as "no hope" by 2 patients, who cited the moving picture "Dark Victory" as their source of information.

Usually patients were more familiar with terms associated with their own illnesses. Patients associated with hospitals in one capacity or another and those hospitalized for long periods of time were able to define more terms correctly.

COMMENT

This investigation indicated that the preliminary examinations were valuable in interpreting the experiences of the patients. Their greatest value lay in estimating the threshold for anxiety. With the stimulus (presentation) more or less constant, the degree of anxiety experienced was a further means of revealing personality structure and the emotional significance of the illness to the patient. The patient's participation in the teaching procedure and the opportunity for him to talk about it led to direct and indirect disclosures of personal concepts of health, of disease and of the emotional significance of disability. These data varied from ignorance and misinterpretation, which had provoked considerable anxiety, to manifest utilization of illness, either consciously or unconsciously, as a socially acceptable outlet for anxiety.

It was indicated that brief explanatory interviews to patients were of considerable aid in avoiding perplexity and correcting misinterpretation. Not only were the patients appreciative of the preliminary interviews, but most of them requested that the essential conclusions of the conference, particularly as they related to their

illness, recovery and return to work, be communicated to them in simple, understandable terms. This can be done best by the house officer who is most familiar to the patient, who has previously explained the procedure to the patient and who has presented the case history. The form and content of this final explanation will vary with the problem, the patient and the nature of the patient-physician relationship. In most instances it is possible to explain the essential program of therapy and the probable period of disability. Opportunity also exists in the latter explanation for the house officer to correct any misinterpretations which the patient may have concerning his illness, medical terms or staff opinions.

This study indicated further that some degree of anticipatory anxiety is inevitable in the presentation of patients. This type of anxiety is not unusual and is probably related to the anxiety experienced by speakers, actors and students before performance or examination. The intensity of the reaction is dependent not alone on the nature of the stimulus but also on concealed or unconscious anxiety associated with the illness. The anxiety may be lessened by means of a preliminary explanation and by tactful and sympathetic presentation. Care should be taken to avoid public presentation of detailed personal and social data in the patient's presence. In many instances these data are not sufficiently relevant to the immediate medical problem and may offend or embarrass the patient. Unfortunately, among lay persons and frequently among physicians, medical students and nurses, emotional factors are equated with moral values. An anxious patient is apt to be considered morally weak as often as he is accepted as a sick person. This was demonstrated in the patients' discrimination in defining "neurotic" and "nervous breakdown." The former connoted intellectual and moral decay, while the latter was interpreted invariably as a socially acceptable state of exhaustion due to overwork. When there are pertinent psychogenic factors, the presentation and discussion may be conducted in the patient's absence. In these instances, the patient may appear briefly for purposes of demonstration or interview. It has been learned that tactful discussion of the interrelationships between psychologic and somatic factors in the presence of certain patients has been of value in initiating emotional as well as intellectual insight. However, the danger of focusing further attention on somatic and visceral symptoms in neurotic personalities is an ever present one.

Unnecessary exposure should be avoided. When there is need for extensive display of the body, loin cloths or trunks should be used.

It was indicated that while the entire procedure of the ward rounds may and should be utilized as psychotherapy, the discussion period has the greatest potential value. In the discussion of certain disorders, the content was understandable to the patient and thus was of aid in enlisting his interest in the care of his disease. This was particularly true of patients who had diabetes, peptic ulcer and arthritis. However, a greater number of patients were more impressed with how the discussants spoke and behaved than with what they said. A sympathetic, confident and reassuring attitude at the bedside helped to allay the patient's anxiety and served to maintain a more adequate patient-physician relationship. While this is dependent on the behavior of the

entire group, it is the responsibility of the presiding physician to establish the rapport.

The bedside manner is the resultant of the patient-physician relationship. Essentially, this is an interpersonal relationship of emotional rather than of intellectual origin. In this relationship the patient identifies the physician with previous sources of emotional security. This identification serves to facilitate the expression of anxiety. Awareness by the physician of his role as a substitute source of security will help him to understand objectively his emotional significance to the patient. With this awareness there will come understanding of the not infrequent extremes of overvaluation or hostility which characterize patient-physician relationships.

SUMMARY AND CONCLUSIONS

The attitude and behavior of 100 patients were studied before, during and after weekly bedside ward rounds. Methods of study included evaluation of personality, observation during presentation and spontaneous discussion and interview following presentation. Pulse, respiration and blood pressure determinations were compared before and immediately after presentation. The patients were classified according to the degree of anxiety associated with their illness and according to the presence or absence of confusion.

No severe emotional trauma was observed. In instances in which the patients were tense or anxious, the reactions were mild and in no way resembled panic reactions. Most patients preferred to be told that they were to be presented. Anticipatory anxiety was experienced by roughly one fourth of the patients. Only 2 patients presented significant fluctuations in pulse or blood pressure. Thirteen patients were distressed by one or more factors during the recitation of the history; 10 patients were distressed by the examination and by the display of charts. Most medical terms and abbreviations were misunderstood or unfamiliar to the patients.

Most patients preferred to remain for discussion, particularly if they had been presented before or if they had seen others presented. Physical discomfort, anxiety or indifference constituted indications for removing patients before discussion.

This investigation indicated that detailed personal and social data should not be mentioned in the presence of the patient; that the discussion period should be used to educate the patient in the care of his disease and that it should serve to foster rapport and confidence in the patient, and that the essential conclusions of the conference, particularly as they are related to the patient's illness, recovery and return to work, should be communicated to him in simple and understandable terms.

It indicated further that brief explanatory interviews before and after each teaching exercise have two purposes: One is to avoid surprise and to correct misinterpretation. The other is to aid in acquainting the house officer with the personality structure of the patient and the degree of anxiety associated with the illness and in establishing a more adequate patient-physician relationship.

Ward round teaching, when conducted tactfully and sympathetically, with attention to the aforestated considerations, is not a traumatic emotional experience to patients but educates and reassures them.

MEDICAL ILLUSTRATION

MAX BRÖDEL

BALTIMORE

This article is a brief attempt to describe the subject of medical illustrating as I see it, state the necessary qualifications of an applicant who wishes to devote his life to this work and tell of the opportunities for success in this field after he has systematically studied the subject and has mastered it in its essentials.

It is agreed that a medical picture, correctly planned and accurately and artistically executed, is an integral part of the medical literature. It not only elucidates the text when needed but may in part even replace it. On the other hand, if not correctly planned or inaccurately drawn, or both, as often is the case, the picture is worse than useless and should be omitted. It is the business of the author of the book or article to eliminate a worthless picture. But it is also the duty of the illustrator to know when a picture is bad. He should realize his responsibility toward the medical profession and never attempt a picture until he is certain that his knowledge and skill are equal to his task.

Every picture should be the work of the artist who signs it. This is not always so. Medical illustrators have learned how to plagiarize; some do it cleverly, others clumsily. It is so easy to lean on others, to borrow or copy another man's picture or a part of it instead of choosing the honest road of original study from nature. Unfortunately the medical literature still contains such plagiarized pictures. It may be stated that economic factors, demanding speed, sometimes force the artist to copy rather freely without giving credit. He is content with a little alteration here and there and calls it a new picture, his own. But he does not realize that old pictures are apt to contain errors, sometimes glaring ones. A plagiarist who is too indolent to seek the truth through original investigation and copies old illustrations with ancient errors perpetuates them. For this reason alone there should be no plagiarism in medical pictures.

Medicine has made enormous strides within recent years. The changes have been both rapid and startling. It is the business of the illustrator to understand them and adapt himself to the new order of things. One of the changes affecting the artist is that photography has entered the field in competition with him. It has come to stay. It threatens to replace the hand made picture, which of course it will never do. True, photography has many advantages over drawing. It is quicker, cheaper and often also more realistic. But a photograph is not a medical illustration in the strict sense of the word. It is a valuable record of something which is easily seen and understood, which is to say the obvious. It fits admirably into a medical or surgical history; it shows clinical phenomena, external lesions, gross as well as microscopic specimens under low, medium and high magnification. Even operations have been shown both in still and in moving pictures. It is stated that a photograph is irrefutable proof of a form or fact under dispute, which of course is not true.

I believe that the illustrator will learn to regard the photographer not as a rival to be feared but as a helpful friend, especially in microscopic drawing, the bane of the medical artist. No longer does his pen have to draw thousands of nuclei, cradled in their elusive cyto-

plasm; no longer does he have to count their number, copy their form and size and also group and space them accurately. To do this all day, every day for months, was a trying ordeal. Fifty years ago there was no mechanical aid, no camera lucida, no photography. All such drawings had to be made by the artist free hand. I have labored over hundreds of them in color, in tone or in pen and ink. But it has done me no harm. Today these sections are all photographed, excepting an occasional section under high power, at which photography has failed in precision.

Photography is now used in every branch of medicine; it is employed with great skill, often to the entire satisfaction of the author and the investigator. It shows form, structure, color and texture, all with complete realism.

But it does not analyze, interpret or teach. It gives no answer to the host of inquiries which plague the student. It makes a dramatic picture, not a scientific one. It rarely shows more than what the photographer has understood, which is rather meager information. There are countless structures in the human body, both small and large, and yet so elusive in form and placement that they escape visual registration almost completely. Their significance is unquestioned and their behavior in health and disease a matter of great importance to medical science. They are there, and yet the eye cannot make them out without close study and observation. The camera in this circumstance is helpless, but the hand-made picture can bring them out with complete fidelity and make them comprehensible to the reader, student, novice and even layman.

Nearly every photograph in the medical literature can be made more valuable by the addition of an explanatory sketch or diagram, a synthetic picture, so to speak, created in the mind of the artist.

A medical picture may even be entirely synthetic and yet be drawn with convincing realism. To make such a picture the artist must know his subject so thoroughly that he can shut his eyes and coax into existence a mental picture of great clarity, complete in every respect. He also must be fully equipped to put this imaginary picture on paper, swiftly, accurately and, if necessary, with convincing realism. This is medical illustrating at its best.

The technic is a matter of choice—halftone, water color, oil, lead pencil, simple or elaborate pen and ink, or a combination of these. It should be remembered, however, that technic, artistic feeling, accurate draftsmanship, neatness and speed are all relatively unimportant. The planning of the picture and the registration of the scientific facts are what gives it its value, not the execution.

As a rule a simple outline drawing is harder to make than an elaborate plastic picture. It is perhaps the most eloquent and useful type of medical illustration. Much information, explanation and analysis can be crowded into a diagram. It may be stripped entirely of all form and structure, relying for its message solely on well chosen key words, figures and numbers, connected by lines and rendered more expressive by the addition of symbols, such as loops, rings, arrows and the like. Even the time element can be graphically shown, also cause and effect, sequence of stages in a disease or an operation. Most instructive pictures can be made that way.

For more than fifty years it has been my privilege to make medical illustrations in all the branches of the field.

Since March 1911 I have also taught medical illustrating at Johns Hopkins University School of Medicine. The experience gained during this long period may be of interest to those wishing to become medical illustrators. I shall try to show that the making of a medical picture is an intricate process, requiring much specialized knowledge and skill. It takes years of preparation to become an artist good enough to serve the medical profession.

A number of institutions now offer courses in medical art, some of them, as far as I can make out, rather sketchy. One instructor even claims to teach the subject in two evenings a week for four months. It should be obvious to any one that such teaching is entirely inadequate. The medical literature must be protected against poor pictures and the pupils from false promises.

HOW I BECAME A MEDICAL ILLUSTRATOR

The art department at Johns Hopkins medical school was the first of its kind in existence. I did not plan it. It came into being through a series of fortunate circumstances which I shall briefly describe.

1. Fifty years ago most medical pictures in textbooks and journals were done by untrained, self-taught artists who knew very little about medicine and less about art. There were no others available, and as a consequence the pictures in the medical literature were of poor quality, far beneath the illustrations in nonmedical publications such as magazines and story books. The draftsmanship of medical pictures was amateurish, the object ineffectively posed and illuminated, sometimes inaccurate in regard to its anatomy and topography. The object evidently was not properly understood by the artist, and the author was unable to help. He probably knew that something was wrong with the picture, but his attempt to suggest corrections usually made it worse. It must be admitted that the atlases were notable exceptions. They were costly tomes, mostly from an earlier period, magnificently illustrated with elaborate copper and steel engravings, later on by lithography, often in gorgeous colors. Much of their beauty was due to the exquisite technic of the engraver or lithographer, not to the artist who made the originals. The same was true of the really fine wood engravings of the early textbooks.

The photomechanical method of reproduction ended this period, and the cheap reproduction of poorly made drawings began.

This was the state of medical illustrating when I entered the service of Dr. Howard A. Kelly on Jan. 18, 1894.

2. I had been fortunate in having received my art training in an academy where meticulous draftsmanship was insisted on and where the graphic arts were included in the curriculum. Both were of great help to me in medical art.

It was also lucky for me to be poor, for I had to seek work during the summer vacations and other free hours throughout the year. I came under the eye of Prof. Carl Ludwig, the great physiologist, and was permitted to illustrate his research and that of his famous pupils. In the course of this work I met Dr. F. P. Mall and Dr. William H. Welch.

3. Luck pursued me. Through Dr. Mall I came to know and work for Dr. H. A. Kelly, whose brilliant work in gynecology marked the beginning of a new era in that field. He chose me to make the pictures for his first large publication, "Operative Gynecology." That was in 1894. I worked hard but with little suc-

cess. Photography was called in to aid in holding the elusive steps in an operation, to produce a clinical picture or show a pathologic specimen. I was urged to accept the help of the camera and obediently did so for a while but soon abandoned its aid, realizing that mere copying of a medical object is really not medical illustrating at all, which, as every medical man knows, goes much deeper than that. Moreover, an artist feels degraded when he copies or uses a photograph as a basis for his drawing.

4. It was fortunate for me that Dr. Kelly was not only a kind and patient chief but also an excellent teacher. He could see that my ignorance in medical matters was a handicap to me. I felt sure that I could draw what I understood but found it exceedingly hard to plan a picture so that any one, even a layman, could understand it. It was difficult for me to select the most suitable view, to determine what to show and how to show it, what to emphasize and what to subdue or leave out. This is where I hesitated and wasted time, as every novice does. It was lucky for me that Dr. Kelly had the remarkable gift of explaining with sketches. In a few simple but graphic lines he could show all the new ideas in connection with his operative work. There is no question that Dr. Kelly's genius for visualization and for sketching paved the way for his illustrators. He made it clear that the conception of a picture is the all important thing, not the plastic elaboration, the realism or the technical finish.

5. Another lucky factor was that Dr. Kelly let me study while working for him. Few employers would permit that. They want pictures for their money. I dissected and injected the pelvic and abdominal organs many times. No drawing was made by me without original study by injection, dissection, frozen section or reconstruction. When variations in adult forms puzzled the eye, the study of embryology gave the key. Many embryos and fetuses were injected, dissected, sectioned and studied. Had these studies been made for me by some one else, in order to save time, I would have benefited little; the finished dissection, injection or reconstruction would still in part have been an enigma to me. The eye and hand must work together to obtain the priceless information that automatically crystallizes into a mental image, which is the forerunner of the subsequent picture on paper. There is no other way, at least for the beginner.

If the artist has thus made sure of his ground, his drawing shows it. It is a truer, bolder, better picture and is done with greater speed.

6. Dr. Kelly also permitted me to help other illustrators while still in his employ. He even encouraged this digression. This paved the way for subsequent teaching of professional illustrators, of art students, medical students and members of the faculty doing research work. There is no better way to learn a subject thoroughly than by teaching it to others. My first pupils, of course, were my friends Becker (1895) and Horn (1898), who came to assist me in the work for Dr. Kelly and his staff. I tried to teach them the fundamental principles of gynecologic illustrating but had little to give in those days. The job was not of my making; it was wished on me. The truth is, we learned together. I was rarely more than a jump or two ahead of them. Confession is good for the soul.

7. Thousands of pictures were made by the three of us to illustrate the various books and articles written by Dr. Kelly and his associates. Each book marked an advance in our method of approach and technic.

It should be stated here that Dr. Kelly also permitted us to make illustrations for other departments—those of anatomy, embryology, physiology, pathology, surgery with its many subdivisions and obstetrics. This outside work retarded our regular illustrating, but Dr. Kelly invariably presented the pictures to his colleagues. This unselfishness broadened my field and ultimately led to the creation of the art department in March 1911. When Dr. Kelly's work ceased, I was tempted to go elsewhere. But my roots were deep in the ground and I was loath to leave Johns Hopkins.

8. This is where my friend Dr. Thomas S. Cullen came in. He had other plans. He had faith in our work, ideals and technic and wanted to keep them at Johns Hopkins. His dream was to create an art department in which the methods and technic which we had evolved during the wonderful Kelly period could be handed down to new generations of medical illustrators and spare them the years of trials and disappointments of their self-taught predecessors.

It is a matter of record that Dr. Cullen did all this single handed. No one else could or would have done it. He succeeded in interesting Mr. Henry Walters in the creation and, later on, in the endowment of a department of "Art as Applied to Medicine" at Johns Hopkins University School of Medicine. Horn had died, Becker's health failed and I was left alone. So it became my privilege to organize and develop this school from 1911 until 1940, a period of thirty years, very happy years to me.

Three names will ever be linked with the Department of Art as Applied to Medicine at Johns Hopkins University School of Medicine:

Dr. Howard A. Kelly, the master surgeon under whom I learned the subject. He laid the foundation for the department.

Dr. Thomas S. Cullen, the man of vision and persistence, who planned it.

Mr. Henry Walters, the keen business man, lover of art and philanthropist, who generously endowed it.

My teaching days are over now. The university, following its custom, has retired me, but I still do the work I love in the department of surgery.

THE ART DEPARTMENT, 1911-1940

During the thirty years of its existence the art department has trained nearly two hundred medical illustrators, carefully chosen from thousands of applicants. There are no two alike. Each has his or her own individual style. I can nearly always tell who made the picture without seeing the signature.

Those who have taken the course are employed in the important medical schools and clinics of the United States and Canada. A few of them are abroad. Their work can be found in the medical literature, exhibits, hospital records, lantern slides and the like.

The size of the class varied from four to twenty-three regular students a year; the average was ten. Every year a few professional illustrators were admitted as postgraduate students for intensive study in a special branch, mostly technic. Members of the faculty and a limited number of medical students received instructions in drawing—the former as an aid in their research, the latter because of their interest in and their talent for drawing and its obvious benefit in the study of medicine.

The instructions of the regular art students, the beginners, were as follows:

Since no illustration can be made without anatomic and histologic knowledge, the student begins in the

dissecting room, doing the work with his (or her) own hands, slowly and thoroughly. Because each student can have only a few bodies to study from, while the range of variations is legion, daily lectures and demonstrations accompany and augment the dissection. A large transparent ground-glass plate covers life size drawings of a skeleton, front, back and side views; also sections, properly coordinated. With charcoal and colored chalk these pictures can be altered before the student's eye to show variations in size, form and proportion due to sex, age or race; also physiologic, pathologic and postural changes, diseases and their course and operations; in brief, everything that concerns the illustrator. Each alteration requires only a few strokes, which are erased when the alteration is demonstrated and another type drawn—and so on.

While the student dissects and studies the skin, the ground-glass plate explains its phenomena in a multitude of variations. Then are taken up the bony landmarks, fat deposits, vessels, nerves, lymphatics and their variations and significance; muscles, tendons, ligaments and fasciae. Then come the internal organs, first in toto, then each organ separately with its variations and pathologic alterations.

Every structure and every organ is studied at the same time microscopically under low, medium and high power to give a complete picture.

The most important part of the student's work in the dissecting room, however, is sketching and drawing. Everything revealed by the student's eye and hand is put on paper immediately, while the impression is fresh. The sketches are made boldly and rapidly in black and colored crayons. Thousands of such sketches are made. They are the test that the student has grasped the subject.

They are valuable to him as forerunners of medical and surgical pictures. He has learned to study the subject in the form of pictures, not of words.

At the end of the year a recapitulation of the topography of the viscera is made by the study of frozen sections, sagittal and transverse.

Fresh material is employed, whenever necessary, to augment the studies on the cadaver and to correct post-mortem phenomena, alterations of form, consistency and color.

Many accessory methods are used to teach the student the correct approach to a problem in illustrating. It is always done in the form of pictures, either on paper, on the ground-glass plate or on the blackboard; occasionally by graphic description, made alive by expressive gestures with the hands. Nearly every discussion terminates with a diagram; a question asked by an alert pupil may lead to the creation of a helpful topographic sketch, sometimes startling in its originality. It is a stimulating habit to show the beginning, course and end result of a disease in an eloquent diagram. The medical literature can use more such pictures.

The student must also learn to make accurate, realistic pictures of objects placed before him. He must know how to pose and illuminate them so that their plastic rendition is simplified.

Much time in the class is given to this part of the training. No artist can create a picture unless he has first learned to imitate nature. Many pictures are made of fresh or hardened specimens from an operation or an autopsy, and, most important of all, realistic pictures of operative steps.

Paralleling these studies are complete instructions in accurate draftsmanship and perfect technic. All important technics must be mastered in order to make the original drawing or painting acceptable to the author, to the engraver and to the publisher. Several new technics were worked out in this department and are taught to the students. The pen and ink technic is by far the most useful, because a line drawing costs less to reproduce and is not easily ruined by inferior presswork.

Being thus equipped, the student is ready independently to plan and make finished pictures for publication. After many failures a moderate degree of success may be attained; occasionally there is a gem, even a little masterpiece.

The superior work of a talented student is quickly noticed by instructor and fellow-students, then by members of the medical and surgical staffs and then by visiting physicians. The student is asked to make drawings for them, which may start him on his way to getting a job.

APPLICANTS

It is generally accepted that medical illustrating is an intricate, highly specialized form of art requiring for its mastery systematic full time study over a period of from two to four years or even longer, according to the talent, speed and preliminary training of the applicants.

They come from colleges, art schools and high schools. I have found that good material may come from any of these.

1. Some applicants are born artists with exquisite technic and a poetic temperament but entirely ignorant of the basic branches of medical science and for some reason quite unteachable.

2. Others have a college background with a fine grasp of the medical aspect of their studies but are awkward in drawing; their eyes and hands do not work together.

3. A rare group of applicants is gifted in science as well as in art.

4. The last group is without talent in either. The applicants of this group assert that they are fascinated by medicine and its dramatic service to humanity and want to help, but mere interest in the subject is not enough. However, there are even here notable exceptions.

The applicant may be a man or a woman. The best age is between 20 and 24.

The qualifications in order of their importance are:

1. Keen interest in science, in nature and in all living things.

2. Ability to study intelligently, to observe accurately and to doubt the statements of authority.

3. Ability to draw and paint from nature free hand and with artistic charm.

4. Ability to visualize, to imagine a picture based on previous study and then give it reality on paper, either in contour alone or with convincing plasticity.

5. Technical skill in drawing, a trustworthy eye guiding an obedient hand, preferably the right.

6. Ability to stick to a task with tenacity and to be resourceful in the face of obstacles.

7. Good general health and normal vision.

OPPORTUNITIES

When a student has shown that he can make a correct and technically perfect picture, some member of the medical profession is apt to discover him and seek his

services. It is not the function of the instructor to find the niche into which he fits best.

While the important medical centers are now provided with the illustrators they need, there always seems to be room at the top. Institutions, clinics, research laboratories, hospitals, surgeons or groups of surgeons are usually interested in hearing of a new and promising artist. Vacancies occur in the ranks of medical illustrators through ill health, death, incompetence and other factors. These vacancies must be filled.

The following branches of medicine require illustrations: embryology, anthropology, anatomy (gross and microscopic), topographic anatomy applied to medicine and to surgery, clinical medicine and microscopy, pediatrics, pathology (gross and microscopic), psychiatry, research (such as on cancer), obstetrics, general surgery and its subdivisions neurosurgery, surgery of the eye, ear, nose, throat and chest, abdominal pelvic surgery (gynecology), genitourinary surgery (male and female) and orthopedic surgery.

An illustrator employed in one of these special fields might rightly be called a specialist, because of the limited range of his activity, and it might be stated that the training for a narrow field could be done in a relatively short time and that therefore a course of two or three years is unnecessarily long, a waste of valuable time. This, however, is not the case.

Every medical artist worthy of the name realizes that he has to know the entire human body and the entire field of medical illustrating before he can discover the branch for which his special talent and his chief interest and inclination fit him best. A medical student does the same and for the same reason.

Moreover, in many institutions an illustrator has to serve several departments and be prepared to draw all types of pictures in every known technic.

REMUNERATION

As every one knows, artists rarely make big money, and a medical illustrator is no exception. His work, if properly done, is an exceedingly important part of medical progress, teaching and dissemination of knowledge and should be adequately remunerated. In many instances, unfortunately, it is not.

It is as difficult to evaluate a fine medical drawing as a successful surgical operation. Is it worth as little as \$10 or as much as \$1,000? Who can say? A drawing is worth what the buyer is willing to pay. That seems to be the only answer. A drawing may look very simple but require a vast amount of thought and a great deal of preliminary study by a conscientious artist who cannot do slipshod work. On the other hand, it may look most elaborate and complex and yet permit of speedy completion.

If the artist is on a regular salary, the work is apt to be of higher quality. If he is paid by the hour or by the drawing, he is inclined to be superficial. There are many other factors causing fluctuations in price:

1. The cost of living where the work is being done.
2. The demands made by the artist because of habit, social status, age, sex.

3. Special gifts, such as originality of conception, exceptional thoroughness and technical skill, large experience, speed, endurance.

It must be admitted that at present it is somewhat difficult even for a talented pupil to find a job. The medical profession has troubles of its own, and many

institutions employing artists are in financial difficulties, but better days will come in due time and with them, I hope, better times for the medical illustrator.

An underpaid artist may find solace in the thought that he does something eminently worth while for the medical profession and, incidentally, also for mankind. He is on the "firing line" of medical progress and should consider it a privilege to be associated with the keenest minds in medicine, the original thinkers, sharing their labors, their hopes and doubts and their ultimate triumphs. And, as I said before, adequate reward usually comes their way in the end. I can assure the beginner that medical illustrating is a fascinating branch of applied art, full of intense interest in all its phases. There is far more satisfaction, I think, in producing a perfect picture which advances medical knowledge—no matter how little—than there is in painting a picture in the modern manner which no man would care to own and which in the last analysis is of doubtful value to mankind in these troublous times.

FRESH COMPOUND FRACTURES

TREATMENT BY SULFONAMIDES AND BY INTERNAL
FIXATION IN SELECTED CASES

WILLIS C. CAMPBELL, M.D.

AND

HUGH SMITH, M.D.

MEMPHIS, TENN.

Preliminary reports of the treatment of compound fractures with sulfonamides with or without metallic internal fixation, and as a rule with primary closure of the wound, were couched in rather conservative terms. After three years of experience with this method, certain favorable impressions deduced in the beginning can now be changed to fairly definite conclusions. The series subsequently to be reported is a representative cross section consisting of 50 private patients treated under optimum surgical conditions with adequate post-operative care and follow-up and 93 municipal hospital patients treated under less favorable conditions. The adoption of this method of treatment is sufficient indication that other routines previously utilized had not been entirely satisfactory.

In addition to the administration of sulfonamides and primary closure of the wound, metallic internal fixation has been utilized in 42 cases. While primary fixation in compound fractures has been used previously and satisfactory results have been reported by others, the safety and wider applicability of the method have been enhanced. The possible adverse effect on the percentage of primary healing by the introduction of foreign material into potentially infected wounds has been largely compensated by the local use of sulfanilamide. Improved metals for fixation, vitallium and stainless steel have been tolerated by the tissues to a much greater degree than the former highly electrolytic alloys. Vitallium was principally used after a thorough trial in open reductions of clean or closed fractures. In a smaller group, stainless steel wire, pins or nails were inserted with essentially the same degree of success.

Dr. Campbell died May 4, 1941.

Read before the joint meeting of the Section on Surgery, General and Abdominal, and the Section on Orthopedic Surgery at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 6, 1941.

Granting that the risk of nonunion or infection is slightly enhanced by the use of internal fixation, the percentage of malposition and shortening, even in the presence of infection or nonunion, is reduced to a minimum. The clinical demonstration that vitallium plates are relatively inert in the tissues has convinced us that the advantages of its use in connection with compound fractures usually outweigh any theoretical objection. The chief advantage of internal fixation lies in the fact that absolute immobilization with anatomic alignment can be secured and maintained without the impediment of cumbersome external fixation. Thereby, the entire injured extremity can be adequately observed and treated without fear of displacing fragments and without further trauma to the damaged soft tissues by movement of the fragments. Further, these fractures are more easily reduced immediately following the injury than at any time afterward. Accurate reduction unquestionably hastens union. Obliteration of dead space and pockets about the ends of the bones diminishes the likelihood of infection.

No attempt has been made to standardize the treatment to one set routine for all compound fractures. For such a method to be practical, injuries would have to be standardized, i. e. the degree of laceration or maceration of soft tissues, the amount of extraneous matter in the wound and the like. Treatment accordingly has varied with the severity of the injury. Those fractures with wounds formed by penetration of the soft tissues from within by the bone fragments were regarded as mild. Fractures produced by rifle or revolver bullets were placed in this category. The group of moderate fractures was those in which the soft tissue wound was extensive but wherein little or no dirt or foreign material had been introduced. The third group of compound fractures, with extensive damage to the soft tissues, with gross contamination by foreign material and with devitalization or obvious imminent necrosis of the soft tissues, was classed as severe fresh compound fractures.

In the treatment of compound fractures the patient's general condition is the primary consideration; on admission to the hospital, emergency measures are instituted to combat shock, hemorrhage and pain. The following points should be determined: the period of time that has elapsed since the fracture, whether the injury is compounded from the outside or has resulted from protrusion of the bones from within out, the extent of the wound, the type of fracture and the extent of injury to blood vessels, nerves, muscles and tendons.

Mild fractures are treated with a relative degree of conservatism. The field and the wound are thoroughly cleansed; a débridement limited to the superficial tissues is carried out, the wound closed and the fracture reduced and immobilized. The wound is not enlarged for the purpose of any extensive exploration or débridement of the depths of the wound. By so doing, additional organisms are introduced into the deep structures and those already present are disseminated.

Pistol shot fractures are treated as closed fractures unless an important tendon, nerve or vessel has been severed. Immediate exploration of the wound and removal of the bullet are more likely to invite infection than external fixation of the fracture followed by massive doses of sulfonamides.

In moderate or severe fractures, the preliminary cleansing process is carried out meticulously, the wound being irrigated and washed with from 4 to 5 quarts (liters) of saline solution. Surgical antiseptics are

applied only to the skin. Strong antiseptics or caustic solutions in the wound coagulate the proteins and cause necrosis of the superficial tissues, thus inviting rather than inhibiting infection. After application of surgical drapes, the wound is enlarged sufficiently for a thorough exploration of the entire wound. After a complete débridement, the irrigation of the wound is carried out again so as to expedite further removal of all foreign material. We are not laboring under the misapprehension or delusion that a sterile wound is the result of the most painstaking execution of this procedure. Rather, we hope to reduce the bacteria, foreign material and necrotic tissue to such a minimum that the natural defense mechanism of the remaining viable tissues, plus sulfonamides locally, will be adequate to prevent an infection.

Complete hemostasis is secured, restricting the use of ligatures to a minimum. Loose particles of bone are left in situ, since large defects between the fragments impede the progress of union. Small particles, with their periosteum and soft tissue attachments intact, may

serve as small grafts and possibly stimulate osteogenesis. Fragments of bone covered with foreign material such as grease or dirt, which cannot be thoroughly cleansed, are an exception to this rule. Metallic internal fixation is applied without hesitancy if it is indicated. From 5 to 20 Gm. of sulfanilamide crystals is then placed in the wound and carefully distributed throughout the entire extent of the wound. In deep and extensive wounds, a few interrupted approximating catgut sutures are used in the deep structures, the skin being loosely approximated with silk. Only under the following circumstances is the wound packed open with petrolatum gauze: (1) when the wound is of more than twelve hours' duration; (2) when the soft tissues have been so extensively mangled that closure of the skin is impossible; (3) when a complete débridement of the devitalized tissues or the thorough removal of all foreign material is impossible, as in a shotgun wound of a fleshy part.

During the latter part of this series we have used sulfathiazole by mouth postoperatively as soon as the nausea ceases, in doses of 1 Gm. every four hours. The use of sulfanilamide locally in the wound, followed by sulfathiazole by mouth, seems to be the most efficient and desirable combination of sulfonamides that

we have tried. No deleterious effects, either to the soft tissues or to the bone, have been noted when sulfanilamide was placed in the wound. In only 1 patient have any serious effects been noted as a result of the use of sulfonamides. In this patient, who had received 39 Gm. of sulfanilamide, bilateral staghorn renal calculi developed that terminated in a fatal pyonephrosis.

From statistical studies, patients who received sulfonamides both locally and by mouth had approximately the same percentage of infection as those who received the drug only by mouth. Despite this, we expect to continue the use of sulfonamides locally; obviously, the greatest concentration in the wound at the earliest possible moment should have a great theoretical advantage in preventing the propagation of bacteria, thereby allowing the natural defense mechanisms to dispense with the remainder. On the contrary, if bacteria have penetrated deeply and an infection is already established before an adequate blood concentration can be built up by mouth, the sulfonamides cannot properly exercise their bacteriostatic and prophylactic effects. The subcutaneous or rectal administration of sulfonamides during the postoperative period of nausea has been discontinued entirely, as the amount of drugs introduced is so small as not to warrant the effort.

In order to evaluate the results of sulfonamide therapy, a comparative analysis was made between the

present group of 143 cases and a consecutive series of 75 compound fractures in which neither internal fixation nor the sulfonamides was used. The results of this study are summarized in table 1. There was approximately the same percentage of union and nonunion, and the average time required for union in the two groups was approximately the same. Primary closure of the wound, in conjunction with sulfonamide therapy, certainly did not increase the incidence of gas gangrene,

nor was there a sufficiently striking decrease in the incidence of gas gangrene to indicate a particularly beneficial effect of the sulfonamides on the gas producing organisms. Of the 5 patients with gas gangrene, 4 lived following amputation; in the other gas gangrene developed following a shotgun wound of the ilium and abdomen, and the patient died.

The incidence of infection was reduced from 33.3 per cent to 18.1 per cent. Only 2 of 143 patients who received sulfonamides died from infection, as compared with 3 in the control series of 75.

Since the possibility of infection in a fresh compound fracture is commensurate with the degree of laceration and maceration of the soft tissues, the 143 fresh compound fractures were further analyzed as mild, moderate or severe (table 2). Prior to the use of sulfonamides, one could reasonably expect healing of the wound without infection in a mild type of compound fracture in a high percentage of cases. Consequently, only 1 infection occurring in 51 mild compound fractures is not considered as conclusive evidence of any beneficial prophylactic value of sulfonamides.

Included in this series of 51 mild fractures were 28 pistol or revolver shot fractures. Twenty-seven of these healed without infection.

Further analysis will be limited entirely to the 92 moderate and severe compound fractures. In this group, 40 patients had internal fixation with 14 infections and 11 nonunions. In the group of 52 with no internal fixation, infection occurred in 11 and in 3 nonunion persisted. These statistics exaggerate the possible theoretical adverse effects of metallic fixation on healing of the soft tissues and the bone, as internal fixation was employed in a group of severe fractures in which a high percentage of infections and nonunions could be expected. There was little difference in the average period of union between those with and those without fixation.

Better anatomic and functional results have been secured by internal fixation in conjunction with sulfonamides. Certainly the 117 patients whose wounds healed following primary closure are in a better residual status than if the wounds had been packed with petrolatum gauze and had healed secondarily with an extensive permanent scar. Even in the 26 cases which became infected, infection could not be considered as severe as compared with the infections prior to the use of sulfonamides. Most of the cases listed as becoming infected did not run a febrile course; nor were there copious quantities of purulent material exuding from the wounds for weeks, associated with emaciation, anemia and sepsis, which would previously have been anticipated. It was also striking that drainage was not as persistent and that wounds in infected cases healed in a much shorter period than one would expect.

We acknowledge the fact that, prior to the use of sulfonamides, thorough mechanical cleansing of wounds and primary closure may have given many good results, but the procedure also eventuated in many acute fulminating infections and disastrous sequelae. Sulfonamides by mouth and in the wound, in conjunction with a meticulous mechanical cleansing and débridement, have definitely broadened the applicability of internal fixation and primary closure to embrace a large group of compound fractures with a commensurate improvement in end results.

869 Madison Avenue.

ABSTRACT OF DISCUSSION

DR. HAROLD R. BOHLMAN, Baltimore: I wish to emphasize a few points in connection with this excellent paper. First, the treatment of shock in these cases and the use of local anesthesia, nerve block or spinal anesthesia to lessen shock. Second, thorough wound toilet with copious lavage, as the authors mention, with removal of all foreign material. Third, the matter of débridement. This word is the most loosely used term in surgery today. How much tissue should be cut away? "Complete débridement" indicates the removal of all traumatized tissue. Too often the surgeon's scalpel does more damage than has the trauma. In a fresh wound how can the surgeon determine with his eye how much tissue to cut away, how much has been actually devitalized? I have treated some 12 patients, derelicts of the streets and alleys, individuals of the poorest class, the poorest risks, without any sterilizing solution on the skin or in the wound, no iodine, no washing, simply reducing the fractures without even washing my hands, putting on a posterior splint, with petrolatum gauze over the wound; raising the blood level of sulfanilamide to 10 mg. per hundred cubic centimeters at once and holding it there; transfusing, if necessary. These wounds have all healed without infections. In some of them we recovered staphylococcus gas bacilli of one type or another, but not a single case of gas gangrene resulted. In many instances in which the skin was greatly macerated it served as a bridge and but little scarring resulted. Fourth, one should make incisions through the fascial planes to avoid internal tension. They should always be longitudinal in the extremities, should open contaminated fascial compartments. Fifth, gas gangrene is a disease of occluded circulation. One must consider the basic circulation in estimating a wound. If it is gone there is no choice but to amputate. Integrity of arterial venous and capillary circulation is necessary. If the slightest pressure occludes the latter and clostridium spores are present in injured tissue, gas gangrene will surely result. Tension must be considered at all times. It must be avoided, whether internal or external, caused by sutures, dressings, casts, petrolatum packs, swelling or by the method of fixation. Sixth, sulfa drugs must be carefully checked and blood transfusions resorted to whenever necessary. In Johns Hopkins since we have been using sulfanilamide prophylaxis in traumatic wounds we have not had a single death since the fall of 1937.

DR. J. E. CANNADY, Charleston, W. Va.: At the Charleston General Hospital we have had a rather extended experience in the use of sulfanilamide applied to and in wounds locally. Altogether we have used this drug in several hundred such cases. In a recent conversation the head of our orthopedic and traumatic department, Dr. H. A. Swart, told me that he has in the last two years treated approximately 50 cases of compound fractures with sulfanilamide locally, following a reasonable cleaning and débridement, and that his results have shown a marked improvement over the cases treated previously without sulfanilamide. Some have said that the application of sulfanilamide or the placing of sulfanilamide in the wound delays healing. I think it does to some extent, though this delay is slight. However, when we measure slightly delayed healing against the possibility of infection I think that the odds are distinctly in favor of the sulfanilamide treated cases. As to delayed healing, I have found that there is somewhat more delay in cases in which large quantities of sulfanilamide have been placed in the wound, but that if the amount used is comparatively small the delay is very slight. I feel convinced that the use of sulfanilamide both in the wound and internally has great value.

DR. HUGH SMITH, Memphis, Tenn.: I purposely avoided any argument relative to the method or Orr and the Carrel-Dakin method in comparison with the present treatment that has been described. I have also tried to avoid any argument as to whether wounds should be or should not be closed. We claim no originality for this treatment and we have no ax to grind; consequently the series was analyzed without prejudice, without bias and without preconception. We do not wish to standardize our method or to eliminate or exclude other methods of treatment. I shall continue to maintain an open

mind about other forms of treatment that may be introduced subsequently, but for the present in civil practice this method has given a better percentage of good results than we previously had. I am willing to say now that if an as carefully analyzed series as this is presented for any other form of treatment I will gladly change. Summing up the treatment, for compound fractures conservatism, for pistol and revolver shot fractures conservatism, for moderate and severe fractures exploration, débridement, sulfanilamide in the wound, fixation if indicated, and closure of the wound, petrolatum-pack drainage or, if one prefers, Orr or Carrel-Dakin methods when thorough débridement is impossible or when closure without extensive tension is impossible because of mangling of soft tissues.

CHICAGO

The treatment of pulmonary or bronchial suppuration is a frequent task of the otolaryngologist who devotes a portion of his time to bronchology. His efforts in this field are identical to his efforts in the treatment of suppurative sinus disease, where they are directed toward restoring the normal physiologic function through establishing and maintaining adequate drainage. The mechanical drainage of the pathologic secretions in the bronchi is accomplished by the action of the cilia, the respiratory movements, the tussive squeeze of the cough reflex, the cough itself and, finally, expectoration. This drainage depends to a large degree on the liquefaction of these secretions by the action of the glands of the more normal bronchial mucosa. That these processes, both the cellular activity and the more gross mechanical ones, may be immeasurably aided by expectorants, by postural drainage and by bronchoscopic suction is well recognized. Means of increasing the efficiency of these measures are readily available; an evaluation of their actions, suggestions regarding their use and new methods which may be employed are herein presented.

The most commonly used means of increasing endobronchial drainage at the present time consist in the administration of one or more of a multitude of expectorant drugs and the age old use of steam inhalations. That these agents are of significance in laryngology and bronchology is apparent from a review of the recent otolaryngologic literature dealing with such subjects as acute laryngotracheobronchitis, bronchiectasis and postoperative massive collapse of the lung. But while they stand the test of clinical trial in a general way, their use is to a large degree empirical. Consequently, to determine the mode and site of action of these widely used therapeutic agents, studies regarding the physiology of bronchial secretions and expectoration were undertaken. These studies, reported in detail else-

where,¹ consisted in physical and chemical analyses of sputum obtained from patients with mild or low grade bronchiectasis. These patients, having a moderately productive cough, were selected because sputum, in any measurable quantity, is a pathologic product and does not exist in a manner in which it can be collected for experimental study in normal individuals. Advanced cases of pulmonary suppuration were not used. By means of postural drainage and bronchoscopic suction, sputum from various parts or levels of the tracheobronchial tree could be obtained and studied independently. It was found that sputum undergoes a series of changes in its course through the bronchi. In the most dependent bronchi its viscosity was found to be greatest. As it advances from these recesses by the tussive squeeze, secretory pressure and respiratory movements to the larger bronchi, it becomes thinner through actual dilution and may be coughed out. The physiology of this process of dilution need not be discussed here. However, it is essential that it be aided to permit adequate, prompt and continuous drainage, because an analysis of the extremely viscous mucopus found in the deepest portions of the bronchial tree suggests that this material plays an extremely important role in the development of bronchopulmonary suppuration. Its presence is confirmed daily in bronchoscopic clinics, and it is discussed in detail by the Jacksons² in their observations on bronchiectatic patients. It is obtainable only through bronchoscopic suction, remaining in the bronchi even after thorough postural drainage. This was graphically demonstrated by serial roentgenograms of the chest of a boy with a saccular bronchiectasis of the right lower lobe. These films were taken before and after postural drainage and then following bronchoscopic aspiration. Anteroposterior and right lateral films of the chest before and after thorough postural drainage showed no change in the radiolucency of the area of bronchiectasis. He was then drained bronchoscopically and a large quantity of this thick pus obtained. A third roentgenogram, taken with the same technic, then showed the areas of radiolucency typical of the disease.

These observations, in a measure, stress the importance of the role which bronchoscopic aspiration plays in the management of bronchopulmonary suppuration. Stagnation of the viscid mucus in the terminal bronchi is in part responsible for the bronchial obstruction leading to the destructive changes which take place in the mucosa of the bronchi to produce bronchiectasis. Unaided, the physiologic process of dilution of secretions, so essential to spontaneous pulmonary drainage, is an extremely slow one. Consequently, a study of the influence of various agents on the bronchial secretions and bronchial mucosa was a logical sequence to the physiologic experiments just mentioned. The pharmacologic actions of expectorant drugs, steam and gases were evaluated by noting their effect on the viscosity, the p_H and the chemical content of the sputum in the major bronchi and on that in the dependent, terminal bronchi, as well as their effect on the mucosa.³ The well known clinical fact that the expectorant drugs and steam lowered the viscosity of expectorated sputum

This work was supported by a grant from the Theodore B. Sachs Laboratory Memorial Fund.

Read before the Section on Laryngology, Otology and Rhinology at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 4, 1941.

was confirmed. However, it was repeatedly found that the most dependent secretions, responsible largely for the destructive changes associated with their presence in the lower bronchi,⁴ were not influenced physically or chemically by these agents.

The manner in which these findings influence various obstructive laryngeal or bronchopulmonary suppurative processes is important in their clinical management. Attention may first be directed to laryngotracheobronchitis because it has been discussed from other angles frequently before this group. As has been pointed out by Richards,⁵ Gittens,⁶ the Jacksons,⁷ Brennemann, Clifton, Frank and Holinger,⁸ the obstructive element in this disease is not alone the inflammatory edema but the secretions and products of inflammation which adhere to the laryngeal and bronchial surfaces. The efficiency of an atmosphere containing a high relative humidity as an expectorant was strikingly apparent in the results of the experiments just described. However, when steam alone is used to attain the desired humidity the temperature of the room, or the croup tent if the child is confined under a closely guarded crib covered with sheets, becomes unbearable and oppressive. The use of a room saturated with moisture produced by a mechanical humidifier was found to be more efficient than one in which steam was used.⁹ Certainly in such an atmosphere expectoration became more efficient.

A second clinical application of this problem is associated with the management of postoperative collapse of the lung. This complication, formerly considered to be a postoperative pneumonia, is now recognized as a distinct clinical entity produced as, Gairdner¹⁰ suspected in 1850, by viscid, inspissated mucus acting as a bronchial plug to obstruct a major bronchus. Its prompt relief by the removal of secretions from the bronchus has been demonstrated innumerable times by all endoscopists. Analysis of this obstructing secretion shows it to have an extremely high measured viscosity which accounts, in part, for the failure of the high normal processes to eliminate it from the bronchi. While bronchoscopic suction is reserved for the advanced stages of this disease, carbon dioxide and other means of increasing both the rate and the depth of respiration have been employed for a number of years by anesthesiologists in removing obstructing secretions and in improving the ventilation of the lung, both before or, if necessary, after bronchoscopy. Even in a prophylactic manner, many surgical clinics use carbon dioxide routinely following anesthesia to aid in preventing postoperative pulmonary complications. Consequently, a study of the influence of this gas on the bronchial mucosa and on secretions seemed indicated. Again using patients with low grade bronchiectasis, carbon dioxide was administered by mask at varying intervals

prior to a bronchoscopic examination. Following the administration of this gas it was noted that the patients consistently had less secretion in their bronchi than they had had without carbon dioxide in spite of the fact that they had not coughed up appreciable quantities. It was also noted that the measured viscosity of this secretion was constantly lower than it had been when carbon dioxide was not used and that there was practically none of the extremely viscid secretion previously noted in the most dependent bronchi. An analysis of the sputum obtained following the use of carbon dioxide demonstrated that an actual dilution had taken place. This was further confirmed by the fact that, together with a lowering of the viscosity of the most dependent, aspirated sputum there was a reduction in its organic and inorganic content. This had not been accomplished either with steam or with the expectorant drugs.

The changes in the character of the mucosa were likewise striking. A definite hyperemia of the bronchial mucosa which was more than "normal" for these areas was noted in the parts of the lung involved in the pathologic process. It was significant that this hyperemia did not involve other parts of the air passages in which the mucosa was normal.

Thus, in a sense, carbon dioxide may be considered as an extremely efficient expectorant. It alone reaches the deeper, very obstructive type of secretion which must be frequently and efficiently drained to prevent serious types of permanent pulmonary or bronchial damage. It is apparent that the action of carbon dioxide is in part dependent on its ability to stimulate an actual resorption of secretions. However, its most important actions are to enforce deeper, more active respiratory movements as well as to liquefy the sputum and stimulate the cough reflex. By evacuating the more dependent bronchi, sputum otherwise inert is brought to a level from which it can be coughed out easily or removed more efficiently by direct suction through the bronchoscope.

The use of carbon dioxide as an expectorant suggests a new and wider therapeutic use for this gas. The following three cases illustrate this action:

O. B., a girl aged 11 years, was admitted to the Children's Memorial Hospital acutely dyspneic and cyanotic. Dyspnea had begun two weeks previously following removal of nasal polyps and was associated with a constant, nonproductive cough. Physical examination demonstrated definite dullness on both sides of the chest and many fine and coarse, bubbling rales throughout. Roentgen ray examination showed an extensive bilateral infiltration extending from the hilus, the most severe involvement being over the middle lobe, which was completely atelectatic. A diagnosis of bronchial asthma, complicated by obstructive pulmonary suppuration, was made. Her cyanosis was relieved by oxygen, but the dyspnea and nonproductive cough continued. Large doses of ammonium chloride and iodides were given, but her cough did not become productive. Thick mucopus was removed by bronchoscopic aspiration, but postural drainage was unsuccessful. The use of carbon dioxide inhalations by mask finally liquefied the secretions shortly after this therapy was instituted and for the first time the child expectorated easily on postural drainage. The removal of secretions bronchoscopically was likewise facilitated. Her improvement has been steady and her chest roentgenograms have shown progressive clearing.

R. J., a boy aged 4 years, had had numerous upper respiratory infections, attacks of bronchopneumonia and asthmatic attacks throughout his life. For the year and a half prior to admission to the Children's Memorial Hospital he had had a productive cough, gradually increasing dyspnea and occasional attacks of cyanosis. Physical examination showed a

slight, undernourished child who was somewhat barrel chested, dyspneic, and on the slightest exertion had some intercostal indrawing. Many bubbling, moist rales were heard over the entire chest. The heart was essentially normal considering the advanced pulmonary involvement. Bronchoscopic drainage was instituted and large quantities of extremely thick, viscid pus were repeatedly aspirated, but he failed to cough it up spontaneously. Because of the high viscosity of the pus present in the trachea and bronchi, first steam and later steam and carbon dioxide inhalations were administered as often as six times a day. Following these administrations he could raise sputum spontaneously during postural drainage. His sputum was definitely thinner. The attacks of cyanosis became fewer in number, and finally there was a decrease in the amount of sputum. It should be mentioned that the use of carbon dioxide in this manner is not contraindicated by attacks of cyanosis unless the cardiac reserve has been greatly diminished. The precaution of limiting its administration to short periods of time in extreme cases should be observed. An expectorant drug, fluid extract of senega, was likewise given.

H. H., a medical resident, sought relief of a dry, unproductive cough which had been present several weeks. He had had no result from the usual expectorants and was unable to raise secretion satisfactorily, which apparently was producing his irritating cough. Mirror examination of the larynx showed a chronically inflamed mucosa. The chest roentgenogram showed a very slight peribronchial infiltration, and the physical examination revealed a few scattered rales in the bases of both lungs. Carbon dioxide inhalations were administered four to five times a day by means of a mask held close to the face for periods of five minutes. Following the first administration he raised a moderate amount of viscid, grayish mucus. Throughout that and the succeeding day expectoration became regular and the material less viscid. It ceased after the third day, and the cough disappeared entirely.

Reviewing in brief the action of carbon dioxide in these three cases, it will be noted that prior to the administration of carbon dioxide even the strongest efforts of the patients to raise obstructing secretions were unsuccessful. The dilution of the secretions and their spontaneous expectoration began only after the carbon dioxide was administered.

Because of the frequent and widespread therapeutic use of oxygen, studies similar to those made regarding the action of carbon dioxide seemed indicated. Physical and chemical changes in the sputum following its administration and bronchoscopic observations of the mucous membranes of the trachea and bronchi were noted. Oxygen was administered by mask or by means of a nasal catheter. Examination of expectorated sputum following various periods of oxygen administration showed an increase in the viscosity of the sputum as well as an increase in its content of organic and inorganic substances. The extent to which these factors had been increased suggested that the action of oxygen had been one of concentration of the sputum. This was confirmed by the bronchoscopic picture. The tracheobronchial mucosa was pale or even blanched in appearance following oxygen administration, and the measured viscosity of aspirated mucus had decidedly increased over the usual measured viscosity of the aspirated mucus of the same patient without oxygen. A clinically important observation was the adherence of plaques of mucus to the bronchial walls, an observation never noted on the same patients without oxygen inhalations. Efforts were made to neutralize this undesired effect of oxygen on mucosa and sputum by the addition of 5 per cent carbon dioxide or steam inhalations administered in conjunction with the oxygen therapy. It was not possible to change the qualities of the sputum with either of these agents alone; only

by combining oxygen with carbon dioxide and steam could this effect be neutralized. Further studies must be made to determine whether higher concentrations of carbon dioxide alone would be as efficient as the combination of steam and 5 per cent carbon dioxide.

These findings become especially significant in the management of obstructive laryngeal diseases as well as in the routine administration of oxygen. As Davison¹¹ pointed out, the use of an oxygen tent in the treatment of laryngeal obstruction complicating laryngotracheobronchitis may defeat the purpose of the oxygen by creating even greater obstruction through the desiccating action of oxygen. To alleviate this, he has provided mechanical humidification for his oxygen tents and has accomplished the desired result in significantly reducing the mortality in his series of cases.¹²

Thus, in a sense, steam or humidification and carbon dioxide may definitely be considered as expectorants of great efficiency, and oxygen an antiexpectorant. Certain drugs, most notably codeine and atropine, fall into this second classification of antiexpectorants as demonstrated experimentally, the former by an increasing, cumulative effect when the drug is repeated daily, the latter by inhibiting secretions for a short time following its administration.

CONCLUSIONS

A certain rationalization of therapeutic procedures used in the management of bronchopulmonary suppurations and obstructions may be suggested to coincide with the bronchoscopic observations and a study of the effect of therapeutic agents on sputum.

In general, it may be stated that factors responsible for liquefying sputum within the bronchi, thus aiding in its evacuation, consist of those agents which will increase the hyperemia of the mucosa, as well as those which will increase the rate and depth of respiration.

The action of the expectorant drugs is almost uniformly favorable in liquefying a portion of the sputum which lies in the first and second division bronchi but rarely affects the dependent viscid secretions in the peripheral bronchi.

The actions of gas inhalations are quite specific, and they grossly influence the physical and chemical qualities of both the expectorated and the bronchoscopically obtainable sputum as well as the character of the bronchial mucosa. Steam inhalation, or the inhalation of a high humidity atmosphere, results in the liquefaction of sputum. Carbon dioxide has an action quite similar to that of steam, but to a greater degree. And, in addition, it increases the resorbing power of the bronchial mucosa; consequently it may be considered an extremely efficient expectorant.

Oxygen acts very specifically as an antiexpectorant and therefore its use alone is contraindicated in obstructive lesions whose obstruction is in part, at least, due to copious, viscid secretions. This deleterious effect may be neutralized partially or wholly through the addition of steam and 5 to 10 per cent carbon dioxide. In this manner not only the tremendous value of oxygen in alleviating the symptoms of respiratory embarrassment or even respiratory decompensation is retained, but also necessary aid in removing the obstruction is administered.

The use of codeine and atropine at regular intervals over long periods of time is contraindicated in

bronchopulmonary suppuration producing obstructive symptoms; however, the use of atropine prior to bronchoscopy may be justified in reducing the total amount of secretion and thus making the procedure easier for the patient.

Specifically, the use of the various agents described may be of distinct advantage in the treatment of certain diseases in manners determined through these studies. In bronchiectasis and in certain types of asthma in which bronchial obstruction plays a role in the symptomatology and pathology, frequent inhalations of carbon dioxide by mask, together with steam inhalations, may be used to augment the postural drainage and bronchoscopic aspiration which are fundamentally important. The use of steam and carbon dioxide between bronchoscopies, and especially shortly prior to bronchoscopy, is indicated if the sputum is known to be extremely thick and tenacious. Such therapy greatly enhances the action of any expectorant drug which is being administered.

In laryngotracheobronchitis, the use of a room kept at 70-75 F. with a relative humidity of 80-95 per cent provides satisfactory conditions for liquefying secretions. If, because of an increasing edema, obstruction of the airway progresses in spite of the removal of secretions, oxygen may become necessary. In such instances adequate provision for a high degree of humidity in the oxygen tent is essential. The attachment of a mechanical humidifier to the tent in the manner suggested by Davison is the most practical means of accomplishing this.

Postoperative massive collapse of the lung, produced by the occlusion of a major bronchus by viscid mucopus, is almost always spontaneously relieved if the patient can be encouraged to breathe deeply and cough. Steam inhalations aid in liquefying secretions and thus facilitate their removal, but carbon dioxide has become the most commonly used expectorant in the treatment of this disease because of its extremely efficient action in increasing the rate and depth of respiration as well as in aiding to liquefy the secretions. Actual bronchoscopic suction when these agents fail, or if the condition of the patient demands immediate intervention, must always be available.

The influence of the agents studied on the mucosa and inflammatory products of the nasal accessory sinuses has not been studied in detail. It remains to be seen whether an inflamed mucous membrane of the upper respiratory tract is similarly responsive to carbon dioxide when this action is not dependent on an actual increase in the respiratory movements.

1819 West Polk Street.

ABSTRACT OF DISCUSSION

DR. H. G. PONCHER, Chicago: Chronic cough has incited therapeutic attempts out of proportion to a great many other symptoms in medicine. There is a tendency to overtreat cough as a symptom, particularly in infants and young children. The points that Dr. Holinger brought out are of particular interest in this phase of practice. When a child or an infant is seriously ill with cough, there is a tendency to put such a patient on opiate-containing cough mixtures or mixtures containing belladonna or atropine or, if the patient is cyanotic, there is the compulsion to resort to routine use of oxygen without first attempting to remove the obstructing factor which produces cyanosis. These procedures Dr. Holinger has shown to be definitely antiexpectorant in action, and any one who has had experience has observed that the patients are sometimes not only not benefited but in some cases actually harmed. The statement

is often made that when a patient receives oxygen through a bottle or a tent there is a sufficient amount of moisture in the gas to prevent any drying of secretion. That, in our experience, is not true. The patients who receive oxygen therapy alone usually have a difficult time bringing up sputum. Dr. Holinger's contribution to this phase of treatment is very important. Not only were we able to get material for examination, but his direct observation of the bronchial tree was important in corroborating changes that were formerly surmised. Carbon dioxide may not only be used in conditions of atelectasis or bronchiectasis but may be extended to the treatment of conditions that formerly never suggested its use. I refer particularly to the treatment of acute bronchitis, in which the sputum is very tenacious and is difficult to raise. The treatment with carbon dioxide results in liquefaction and thinning of the secretion, so that the child is able to breathe freely and raise the material. Severe asthma in children is much improved by the use of carbon dioxide. Other conditions, like pertussis, in which the infant or child almost strangles on thick, tenacious mucus, are also definitely benefited by such therapy in conjunction with moist air. I would like to emphasize again the important clinical implications that Dr. Holinger brought out; the routine use of atropine and belladonna derivatives, opiates and oxygen without carbon dioxide and moist air should be condemned, and the beneficial effect of pure carbon dioxide inhalations in conjunction with moist air in conditions which ordinarily do not respond to the usual expectorant measures.

Clinical Notes, Suggestions and New Instruments

CEPHALIC TETANUS ACCOMPANIED WITH PARALYSIS OF THE FACIAL NERVE AND GEN- ERALIZED TETANUS

WILLIAM W. TRIBBY, M.D., AND CARROLL H. LONG, M.D.
NEW ORLEANS

Only 12 cases of cephalic tetanus accompanied with paralysis of the facial nerve have appeared in the American literature, although well over 100 instances have been reported in foreign publications. In 1895, Willard¹ reviewed 74 cases of cephalic tetanus and reported the first case in America associated with paralysis of the facial nerve. In 1907 Eastman² wrote a short review of the cases reported by Willard,¹ Lange³ and Lloyd⁴ and added 3 previously unrecorded cases. He included reports on only those cases in which there was paralysis of one or more cranial nerves. The only other review of the American literature has been that of Brown,⁵ who in 1912 found 93 cases reported in the world literature and added 1 of his own. Since that time 1 case has been reported by each of the following authors: Carson,⁶ Carr,⁷ Lewis,⁸ Gray⁹ and Watkins.¹⁰ In addition to these reports, we have found 3 cases of cephalic tetanus without paralysis of the facial nerve. Irvin¹¹ reported a case of generalized tetanus which followed a severe injury to the right eye. Bishop, Du Bosc and Hamlin¹² reported a

case of otogenous cephalic tetanus and Hyman¹³ a case which followed tonsillectomy. The number of cases is not great enough to justify a statistical analysis.

REPORT OF CASE

First Admission.—H. W., a white man aged 28, a farmer, was admitted to the Charity Hospital on May 18, 1940. Six days before admission he had been standing in his barnyard knocking mulberries out of a tree with a stick; the stick fell back and struck his face, causing what appeared to be two small abrasions on the right cheek. Two days later the injured site became painful, red and swollen. Hot compresses were applied, and pus was expressed in small amounts daily thereafter.

The temperature was 100.2 F., the pulse rate 92 a minute, the respiratory rate 20 a minute and the blood pressure 135 mm. of mercury systolic and 85 mm. diastolic. The patient was tall, well developed and well nourished and did not appear acutely ill. There was an intensely red, warm, indurated swelling of the right cheek, about 4 cm. in diameter. An area 1.5 cm. in diameter, in the center of the lesion was fluctuant. Removal of a small crust allowed about 2 cc. of thick yellow pus to escape. The superficial and deep reflexes were normal. The blood showed hemoglobin 80 per cent (Tallqvist), red blood cells 5,000,000 and white blood cells 8,000 with a normal differential count. A Kline test of the blood gave negative results.

The patient was treated continuously with hot compresses of physiologic solution of sodium chloride applied to the right cheek. A small rubber dam was inserted into the lesion for twenty-four hours. Although moderate amounts of pus continued to drain from the abscess, the cellulitis subsided in three days and the patient was discharged from the hospital. He did not receive tetanus antitoxin.

Second Admission.—The patient returned to the outpatient clinic on May 27, fifteen days after the injury, and was readmitted to the hospital. He complained that pain in the lower part of the back, of two days' duration, was exaggerated by walking and by movements of the trunk. At home he had applied hot saline compresses to the right cheek, but pus, although thinner, had continued to drain from the wound. Gradually, in the period of the three days preceding his second admission, he had become unable to open his mouth, move the muscles of the right side of his face or close his right eye.

The rectal temperature was 101 F. and the pulse rate 106. The patient appeared acutely ill. His face was flushed and he was perspiring freely. He was easily startled but was mentally alert and cooperative. There was complete peripheral paralysis of the right facial nerve. He was unable to whistle, elevate the right eyebrow or show his teeth on the right side. The right eyelid could not be closed. Movements of the left side of the face were intact. He was able to open the mouth a distance of about 2 cm. on the left side, but movement of the right jaw was more restricted. The abscess of the right cheek was surrounded by an area of induration about 2.5 cm. in diameter. Thin yellow pus could be expressed from the central opening. Inspection with a small probe revealed a narrow cavity extending downward and to the right a distance of approximately 2 cm. There was some stiffness of the neck. The chin could be flexed passively on the chest with the production of great pain. There was slight spasticity of the abdominal and back muscles. The arms and legs were relaxed with difficulty, and the patient moved them in an unsteady, jerky fashion. The deep reflexes of the Achilles and patellar tendons were hyperactive. There was a slight increase of the left knee jerk over the right one. Sustained ankle and patellar clonus was present. A spinal puncture revealed normal conditions. The white blood count was 9,750, with 80 per cent polymorphonuclear leukocytes.

The diagnosis of tetanus was suggested by trismus, hyperactive reflexes and muscular spasticity. These signs became exaggerated the day following admission with the onset of

attacks of severe generalized pain in the back, lasting one to two minutes, at which times the patient's body became opisthotonic with rigid extremities and a boardlike abdomen. No difficulty in swallowing was experienced. These attacks were precipitated by slight stimuli such as unexpected questioning or movement of the bed.

The local lesion was treated with daily applications of zinc peroxide paste, but repeated cultures of pus from the abscess demonstrated the presence of *Staphylococcus pyogenes albus*, *Clostridium welchii* and *Escherichia coli*. On May 31 the abscess pocket was incised, and a splinter of wood about 1.25 cm. in length was found embedded deep in the tissues. *Clostridium tetani* was cultured from this. Tetanus antitoxin was administered as follows: On May 28, 60,000 units was given intravenously and 40,000 units subcutaneously, on May 30, 100,000 units intramuscularly, on May 31, 60,000 units subcutaneously, on June 2, 60,000 units subcutaneously and on June 4, 100,000 units intramuscularly, a total of 420,000 units in a period of eight days. Each dose of antitoxin was followed on the next day by temporary diminution of the tetanic symptoms, but it was deemed wise to discontinue its use on June 3 because of the appearance of urticaria on the arms and the upper part of the chest. Avertin with amylene hydrate was administered rectally as needed, this being the only means of obtaining complete relaxation and sleep.

Early on the morning of June 6, the rectal temperature was 105.4 F., the respiratory rate was 36 and respirations were shallow; the pulse rate was 150 and the blood pressure 150 systolic and 60 diastolic. There was an occasional dry cough, but no signs of consolidation were elicited in the chest. Two days later, reexamination of the chest revealed bronchial breathing and a few fine rales at the base of the right lung. A diagnosis of bronchopneumonia at the base of the right lung was confirmed by a roentgenogram. Pneumococci were not found in the sputum. The white blood cell count was 12,450 with 86 per cent polymorphonuclear cells. Therapy with sulfapyridine was started on June 8 with an intravenous dose of the sodium monohydrate and was continued by mouth for eight days thereafter, until the temperature reached normal. The concentration of sulfapyridine in the blood on June 10 was 8.4 mg. per hundred cubic centimeters, and on June 11 it was 10.5 mg. The signs and symptoms of pneumonia and tetanus began to subside gradually, the decline coinciding with the administration of sulfapyridine. On June 12 the patient was able to move his neck and extremities with ease, although the abdomen was still spastic. He continued to have occasional mild convulsive seizures until June 13. Diminution of the trismus and slight improvement of the paralysis of the facial nerve were first noted on June 16. Neurologic examination just before his dismissal on June 24, forty-three days after the accident, revealed somewhat hyperactive tendon reflexes and slight spasticity of the abdominal muscles. There was no stiffness of the neck. The clonus of the ankle and patella had entirely disappeared. The patient could open his mouth about 3 cm. and could wrinkle the forehead and elevate the eyebrows, although there was a definite weakness of the facial muscles on the right side. The right eye could be closed, and blinking was present in it but not complete. The abscess of the face was healing rapidly. The patient was last seen in his home on August 28 by one of us and had completely recovered.

COMMENT

We add the thirteenth case of cephalic tetanus accompanied with paralysis of the facial nerve to the American literature. This type of tetanus is either rare or has not been recognized in this country. In the differential diagnosis of this case, tetanus might have been overlooked if generalized symptoms had not ensued. Tetanus should be kept in mind whenever there is paralysis of the facial nerve following a facial injury, especially when it is accompanied by trismus, for paralysis of the facial nerve may be the first symptom of early cephalic or generalized tetanus. The possibility of the presence of a foreign body in any wound should not be overlooked.

13. Hyman, S.: Head Tetanus Following Tonsillectomy with Subsequent Recovery. *Am. J. Dis. Child.* 49: 1540 (June) 1935.

Our patient's condition was grave, and he showed no decisive improvement until a relatively high level of sulfapyridine was obtained in the blood stream. The drug was administered because of bronchopneumonia but may have had a favorable influence on the course of the tetanus. The work of Mayer¹⁴ gives us some basis for this belief. This author administered sulfanilamide and sulfapyridine to a small series of mice and apparently demonstrated in them a high degree of protection against tetanus. He administered the drugs by mouth, beginning immediately after subcutaneous injections of tetanus bacilli and spores.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

THEODORE G KLUMPP, M.D., Secretary

NOMENCLATURE OF NONCRYSTALLINE ESTROGENIC PREPARATIONS

The Committee on Nomenclature of the Council on Pharmacy and Chemistry has been considering for some time the adoption of an official term to signify preparations containing estrogenic substances which are not in a pure chemical state. The need for such a nomenclature is obvious since the market contains numerous preparations of noncrystalline estrogens, and the multiplicity of proprietary terms for such products has been quite confusing to physicians. The rectification of this confusion is essential for discriminating between the crystalline and the noncrystalline preparations. The Council therefore adopted the following terms to signify noncrystalline estrogenic substances which contain principally estrone together with other estrogenic substances obtained in the extraction process: Solution of Estrogens or Solution of Estrogenic Substances. If the preparation is in a form other than solution, the appropriate term may be substituted for "Solution," such as Suppositories of Estrogens or Estrogenic Substances, Tablets of Estrogens, and so on.

The Council will require that such preparations be designated by either of these names for inclusion in New and Nonofficial Remedies. Also it will be necessary to state beneath the title the source of the preparation, such as whether it is from pregnant human urine, pregnant mares urine or placenta, and the predominant estrogenic substances.

The Council has already accepted such a noncrystalline preparation, namely Amniotin (Squibb). The Council has recognized this firm's right to Amniotin as a proprietary term.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

THEODORE G KLUMPP, M.D., Secretary.

EPINEPHRINE-U. S. P. (See New and Nonofficial Remedies, 1941, p 252).

Suprarenalin (Armour) (See New and Nonofficial Remedies, 1941, p 253).

The following dosage form has been accepted:

Suprarenalin Solution 1,000 in 5 cc vials (for hypodermic use). Contains suprarenalin (epinephrine) as hydrochloride 0.10 per cent, chlorobutanol (chloroform or chloral derivative) 0.50 per cent, sodium bisulfite (not more than) 0.10 per cent, physiological salt solution q s.

DIGITALIS (See New and Nonofficial Remedies, 1941, p 204).

The Wm. S. Merrell Company, Cincinnati.

Digitalis Tablets, 1½ grains Merrell—Each tablet is equivalent to 1 U. S. P. unit.

¹⁴ Mayer, R. L. Action of Sulfanilamide and Sulfapyridine on Tetanus Bacilli and Toxin, *Compt. rend. Soc. de biol.* 130: 1560, 1939

THEOPHYLLINE WITH ETHYLENEDIAMINE (See New and Nonofficial Remedies, 1941, p 583).

The following dosage forms have been accepted:

Ampules of Aminophylline, 2 cc, 0.48 Gm (7½ grains). Each ampule contains aminophylline 0.48 Gm and benzyl alcohol 0.04 cc in sufficient distilled water to make 2 cc.

Prepared by the Lakeside Laboratories, Inc., Milwaukee.

Ampules of Aminophylline, 10 cc, 0.24 Gm (3¾ grains). Each ampule contains aminophylline 0.24 Gm in sufficient distilled water to make 10 cc.

Prepared by the Lakeside Laboratories, Inc., Milwaukee.

Tablets of Aminophylline, 0.1 Gm (1½ grains).

Prepared by the Lakeside Laboratories, Inc., Milwaukee.

ASCORBIC ACID (See New and Nonofficial Remedies, 1941, p 557).

The following dosage forms have been accepted:

Tablets Ascorbic Acid Breon, 100 mg.

Prepared by George A. Breon & Co., Inc., Kansas City, Mo.

Tablets Ascorbic Acid-Breon, 25 mg.

Prepared by George A. Breon & Co., Inc., Kansas City, Mo.

Ascorbic Acid Tablets Stearns, 50 mg.

Prepared by Frederick Stearns & Company, Detroit.

Ascorbic Acid Tablets Stearns, 100 mg.

Prepared by Frederick Stearns & Company, Detroit.

MERCURY OXYCYANIDE (See New and Nonofficial Remedies, 1941, p 348).

The following dosage forms have been accepted:

Ampules of Mercury Oxycyanide 0.008 Gm (¼ grain), 5 cc. Each 5 cc contains 0.008 Gm mercuric oxycyanide N. N. R. dissolved in distilled water.

Prepared by the Lakeside Laboratories, Inc., Milwaukee.

Ampules of Mercury Oxycyanide 0.011 Gm (¼ grain), 5 cc. Each 5 cc contains 0.011 Gm mercuric oxycyanide N. N. R. dissolved in distilled water.

Prepared by the Lakeside Laboratories, Inc., Milwaukee.

PONTOCAINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1941, p 77).

The following dosage form has been accepted:

Pontocaine Base Eye Ointment. An ointment containing 0.5 per cent of pontocaine base, the free base of pontocaine hydrochloride, dissolved in white petrolatum.

Prepared by the Winthrop Chemical Co., New York.

SULFANILAMIDE-NATIONAL DRUG CO. (See New and Nonofficial Remedies, 1941, p 508).

The following additional dosage forms have been accepted:

Sulfanilamide National Drug Co., Tablets, 1 grain.

Sulfanilamide-National Drug Co., Tablets, 7½ grains.

SULFATHIAZOLE (See New and Nonofficial Remedies, 1941, p 519).

Sulfathiazole-Lilly.—A brand of sulfathiazole-N. N. R.

Manufactured by Eli Lilly and Company, Indianapolis. U. S. patent applied for. No U. S. trademark.

Tablets Sulfathiazole Lilly, 0.25 Gm (3¾ grains).

Tablets Sulfathiazole Lilly, 0.5 Gm (7½ grains).

LUNOSOL (See New and Nonofficial Remedies, 1941, p 497).

The following additional dosage form has been accepted:

Liquid Lunasol—An aqueous solution containing 100 Gm of lunosol in each hundred cubic centimeters. One cc of liquid lunosol is equivalent in silver chloride content to 1 Gm of lunosol.

This concentrated aqueous solution of lunosol is marketed in ½ and 2 ounce dropper bottles, accompanied by an empty dilution bottle, thus affording a convenient means of preparing the various dilutions which may be indicated, also in 1 ounce and 4 ounce bottles for dispensing.

SUSPENSION OF EPINEPHRINE IN OIL 1:500-N. N. R. (See New and Nonofficial Remedies, 1941, p 255).

EPINEPHRINE IN OIL 1:500-ENDO—A brand of suspension of epinephrine in oil 1:500-N. N. R.

Manufactured by Endo Products, Inc., Richmond Hill, N. Y. No U. S. patent or trademark.

Ampoules Epinephrine in Oil 1:500 Endo, 1 cc.—A suspension of 2 mg of epinephrine base in 1 cc. of peanut oil.

PROCAINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1941, p 80).

The following dosage form has been accepted:

Hypasol Solution Procaine Hydrochloride 2%, 2 cc. Ampoules containing 0.04 Gm of procaine hydrochloride dissolved in sufficient physiological solution of sodium chloride to make 2 cc.

Prepared by The Drug Products Co., Inc., Long Island City, New York.

THE MILITARY EMERGENCY AND THE MEDICAL PROFESSION A Statement by Major General James C. Magee, Surgeon General, U. S. Army

In the present military emergency, the Medical Department of the Army must look for the greatly increased numbers of medical, dental and veterinary officers required for military service to the professions as established and practicing in civil life. That this fact has impressed itself with full force on the minds of the civilian members of the professions is attested by the many inquiries, proffers of service and suggestions directed toward a solution of the problems involved coming from all sections of the nation.

The magnitude of the military effort demands the separation of thousands of practitioners from their accustomed occupations, and the same holds true of those who are engaged solely in administrative and instructional lines of endeavor. It is patent, in view of the administrative policies now applicable to the procurement of officer personnel whereby the choice of individuals for service is almost entirely restricted to those at present holding Reserve commissions, that certain dislocations will take place in communities and organizations that will be regarded as, and in fact will be, hardships to those concerned. A broadened base from which to draw officers for duty would of course serve to ameliorate the situation.

In the present emergency it is difficult to be specific as to the manner in which medical schools may best serve military interests. Within recent weeks the War Department liberalized its policy in reference to the deferment of military service for medical students by granting authority to commission members of the junior and senior classes in the Medical Administrative Corps, so placing them under the control of the Surgeon General. Students accepting such commissions can be held in deferment; on graduation they can be commissioned in the Medical Corps Reserve and, on completion of one year's internship, ordered to active duty in their capacity as physicians. While this arrangement is not ideal it is

helpful and, if the principle is rigidly followed, should serve to make available a large group of young physicians each year who can be best spared from civil life, so leaving in their communities a like number of more necessary and more perfectly established older men. In this respect medical schools can be very helpful by urging their students to seek commissions in the Medical Administrative Corps when eligible.

Because many members of medical school staffs hold Reserve commissions, some of them will be sought for military service. It is not the desire of the Surgeon General to disrupt any essential established institution or program by the withdrawal of key personnel and, whenever conditions will permit, deferment will be granted such persons. However, if this policy is to become applicable to any effective degree, it becomes incumbent on the administrative heads of such institutions to consider carefully their lists of personnel, evaluate each individual's qualifications in reference to the needs of the institution and of the Army, and request deferment only for those who are in fact essential staff members whose separation would entail real hardship.

Many medical schools have generously offered the use of their facilities for the advanced training of officer personnel and for the training of enlisted technicians. A splendid field, susceptible of development to the great good of the Medical Department, is here available should our necessity become so acute as to warrant acceptance of these proposals. At present, however, the organization and operation of the department are such that it is not practicable to adopt these methods and we must look on the medical schools, in this respect, as a reserve to be made available when needed.

One great contribution to the medical effort is being made that deserves comment. It is to be found in the splendid work being done by members of various advisory boards and committees now engaged in military

medical activities in liaison with the Surgeon General. These gentlemen are in most instances connected with our great medical teaching institutions and in that capacity bring to their tasks not only their own high talents but the names and prestige of their schools as well. This in itself is a great support and aid to the Army Medical Department.

It is impossible to foresee at present the ultimate demands to be made on the several professions engaged

in the healing arts in our country nor is it possible now to prophesy what changes in procedure may become necessary in reference to the employment of professional personnel, but it is certain that the medical schools of the nation will continue in the very first rank of those agencies engaged in the preservation of the American medical tradition through complete support to the military forces.

August 12, 1941.

FORTY-FIRST ANNUAL PRESENTATION OF EDUCATIONAL DATA BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

A summary, statistical and editorial, of the educational activities of the Council on Medical Education and Hospitals is presented annually in the Educational Number of *THE JOURNAL*. In the following pages will be found the report for the academic year 1940-1941, the usual review of preliminary and undergraduate education, a description of the approved medical schools of the United States and Canada, revised lists of hospitals approved for the training of interns and for residencies and fellowships in the specialties, and an audit of what is being done, and by whom, throughout the various states to extend opportunities for the advanced education and continued training of practicing physicians. In this section is a descriptive account of numerous clinical societies and educational organizations engaged in all types of graduate and postgraduate medical education. The major national defense regulations, as far as they affect medical education and medical students, are reproduced in a readily accessible form. Finally are included the official requirements of each of the fifteen approved examining boards in medical specialties, together with figures showing the numbers certified to date.

The Educational Number of *THE JOURNAL* has proved to be an indispensable source of information for students, interns, residents and practicing physicians and those interested in specialty certification. It interests also presidents of universities maintaining medical schools, the deans and other officials of medical schools, licensing agencies, the directors and staffs of hospitals, and the various general and special societies interested in the promotion of graduate and postgraduate medical education. It is in frequent demand by governmental agencies. In addition to the circulation of *THE JOURNAL*, almost two thousand reprints of the entire study are distributed, and an equal number of separate reprints of the lists of hospitals.

All these data are based on current official reports. Acknowledgment is tendered the officers of the institutions mentioned and others for their ready cooperation in supplying the material presented herewith and for other records furnished throughout the year to the office of the Council and the members of its staff on inspection or visitation, enabling the Council to maintain its medical student and hospital registers efficiently and to carry on its activities as outlined by the House of Delegates of the American Medical Association.

DEFENSE ACTIVITIES

Leaders in education acknowledge the paramount importance of national defense. National defense, however, includes not only military preparedness but also the preservation and development of all institutions necessary for the safety and welfare of the people. An effective program of national defense, therefore, demands that educational institutions which provide a

continuous supply of men skilled in professions, notably in medicine, be maintained unimpaired. To this end the Council on Medical Education and Hospitals has been frequently in conference with the medical services of the army and navy. Through its Committee on Medical Preparedness, the American Medical Association has rendered and continues to render every possible assistance.

Medical Schools.—The faculties of medical schools have been classified with respect to availability for medical service in national defense. An alphabetical list of essential faculty members was supplied the Surgeon General of the United States and the commanding officer of each corps area in the fall of 1940 and was subsequently revised as occasion required. In the majority of cases reserve officers who occupy essential positions on the faculties of medical schools have been deferred for a reasonable time until a replacement can be secured or until a teaching assignment has been completed. It has been suggested by the office of the Surgeon General that, in order to maintain uninterruptedly the instruction of medical students, those members of medical faculties who are essential should not at the same time hold commissions in the Reserve Corps and, more especially, should not be assigned to affiliated hospital units. The War Department expects that when an affiliated unit is called to active service every officer should be able to go, as there has been time to arrange for others to take over his civilian responsibilities.

At a meeting of the executive council of the Association of American Medical Colleges, held in Chicago, May 30, 1941, three recommendations were made and submitted to member colleges of the association and to the Council on Medical Education and Hospitals. These were:

The Executive Council recommends that those schools which can do so, without lowering standards of medical education, increase the enrolment of the 1941 entering class by 10 per cent in order to help meet the medical needs of the present national emergency.

The Executive Council recommends that the Association urge every medical college which can do so, without lowering standards of medical education, to continue the required medical training of the fourth year during the summer of 1941 in order to graduate at an earlier date as many students as possible.

The Executive Council recommends that the Association make a study of the need for and the possibility of revising the schedule of instruction in medical colleges with a view to accelerating the output of graduates during the national emergency without any lowering of standards of medical education.

The Council on Medical Education and Hospitals expressed the opinion that, as some schools have for many years operated on the quarter plan, formal action

approving this procedure was not needed at present. In the absence of any definite information from the War Department as to the necessity for increasing enrolments or accelerating the output of medical graduates, the Council took no action on any of these matters.

Forty-four medical schools have increased the enrolment of the 1941 entering class by a total of 329 students. It is anticipated that the sophomore enrolment will be increased 40, juniors 131 and seniors 79. Eleven schools have made it possible for students to anticipate, during the current summer, a part of the required work of the fourth year. In three of these schools the program is required. Classes will be graduated in February or March by eight schools. Three schools will allow seniors to finish their work two months earlier and begin their internship or other work at that time, but they will graduate with the regular class in June. Two schools are planning to operate on the four quarter plan.

The medical curriculum has not thus far been curtailed, although the total time involved has been shortened by cutting down vacations. Additional courses in military medicine are being offered. The medical schools, apparently, are able to proceed without extensive revision of the curriculum and without shortening the period of residence. An accelerated program is not possible in many institutions for various reasons, including the fact that their teaching force has been reduced for military reasons. Others would consider such a program if completion of the course could be integrated with hospital internships. The financial aspect is an important consideration both for students and for schools.

Medical Students.—In the Selective Service Act of 1940 there was no provision for the exemption or deferment of medical students as such. Like all other students, they were placed in class I-D which granted them deferment until approximately July 1, 1941. On May 4, 1941 deferment from military training of individual medical students was recommended by Brig. Gen. Lewis B. Hershey, deputy director of Selective Service. But the actual decision, under the law, rests with the local boards. The release from the national headquarters of the Selective Service System reads as follows:

FOR RELEASE: SUNDAY, MAY 4, 1941

Moving promptly to meet a "growing national shortage of physicians and surgeons," reported by the Office of Production Management, a policy of deferment from military training of individual medical students "who give reasonable promise of becoming acceptable medical doctors" was proclaimed today by Brig. Gen. Lewis B. Hershey, deputy director of Selective Service. These deferments should be continued in each individual case so long as the student is progressing satisfactorily, he said.

General Hershey's memorandum, which summarizes the report of the OPM, was sent to all State Selective Service Directors for communication to their local boards. It stresses the OPM statement that the shortage of physicians and surgeons affects both the nation's armed forces and the civilian population and that the utmost care must be exercised to meet both needs.

Local boards are urged to see that, while no practicing doctor whose services are necessary to his community is called for military service, the requirements of the armed forces for physicians and surgeons also are filled. It also is stressed that where doctors, including interns, are eligible for military service they should be encouraged to apply for Medical Reserve Corps commissions, but that they will be inducted if they are placed in class I-A and fail to take advantage of the opportunity to be commissioned. In the case of interns, it was pointed out that, if commissioned, they will be permitted by the War Department to complete one year's internship.

Summarizing the OPM report on its study of the situation, General Hershey pointed out that it indicates a present need of around 9,000 medical officers for the Army, Navy, Public Health Service and Veterans Administration in addition to present staffs. This approximates a reduction of about 5 per cent in the number of doctors now available for service in civilian life, and it is estimated that the further demand caused by health problems in communities expanded by new defense industries will increase this civilian need to about 10 per cent.

In addition to the 9,000 additional medical officers required by the Army, Navy and other agencies, General Hershey said the OPM report showed a probable annual turnover of around 3,500 because of retirement of Regular Medical Officers and the expiration of tours of duty of Reserve Medical Officers.

The OPM report estimates that there are 155,000 practicing physicians in the United States, of whom about 27,000 are 65 years of age or older, and the mortality is around 3,800 a year. Their places can be filled only by medical graduates who enter the profession each year and their number is estimated at approximately 8,000, of whom only 60 to 65 per cent probably would be qualified physically or otherwise for military service.

Commenting on this situation in announcing the Selective Service policy of deferring medical students who are making satisfactory progress in their professional training, General Hershey's memorandum to state directors stated:

"There are no replacements for medical students who are withdrawn from school. Consequently if the supply of medical students who are to be graduated into the medical profession is reduced through their induction to serve in a nonprofessional capacity, an increasing reduction of physicians available for military service as well as an aggravation of the increasing overall national shortage will result."

As an outline of policy and procedure for the Selective Service System concerning medical students, General Hershey quoted the OPM report:

"It is of paramount importance that the supply be not only maintained but encouraged to grow, and that no student or intern who gives reasonable promise of becoming an acceptable medical doctor be called to military service before attaining that status."

Local boards were cautioned, however, that a deferment is not an exemption and that the obligation and liability for military service remain on its expiration.

General Hershey's memorandum also called attention to a previous one issued on April 22 prescribing procedure for deferment of individual students in a number of specialized professional fields which were suggested by the Office of Production Management. This memorandum suggested procedure for presenting local boards with detailed facts concerning individual students which was prepared by the American Council of Education and concurred in by National Headquarters of the Selective Service System. As set forth in a bulletin (No. 10) issued by the Council, this provides for getting into the hands of the local board of a "Student Statement of Information" concerning his status and plans and an affidavit by his college or university in which the college officials testify as to his standing, courses and occupational objectives, together with a general evaluation of the student as a "necessary man" for occupational deferment.

By recent amendment of paragraphs 352 and 353 of the Selective Service Regulations a new class has been introduced; namely, class II-B, which assures the student deferment as long as his status remains unchanged.

Amendment No. 59, effective June 5, 1941, amends Volume Three, section XVIII, paragraphs 352 and 353 of the Selective Service Act of 1940, to read as follows:

352. *b.* In class II-B shall be placed any registrant found to be a "necessary man" in any industry, business, employment, agricultural pursuit, governmental service or any other service or endeavor, or in training or preparation therefor, the maintenance of which is essential to the national health, safety or interest in the sense that a serious interruption or delay in such activity is likely to impede the national defense program.

353. *b.* Class II-B deferments shall not be limited as to the period during which they shall be effective. The case of a registrant classified as class II-B may be reopened and his classification considered anew in the same manner and for the same reasons as any other classification.

The House of Delegates of the American Medical Association after a joint conference of the Committee on Medical Preparedness of the American Medical Association and the Council on Medical Education and Hospitals, held June 2, 1941, urged the War Department to provide for all medical students in approved medical schools and for premedical students some form of military status which will make clear the fact that, in preparing themselves to become physicians for the services of the country, these students are already actually giving an essential service under the preparedness program and are not seeking to evade, escape or defer their responsibilities.

On May 26, 1941 authority was granted for the commissioning as second lieutenants in the Medical Administrative Corps Reserve, after July 1, 1941, male junior and senior medical students in approved medical schools who are fit for military service; also for commissioning interns as first lieutenants, Medical Corps Reserve, with the understanding that they will be ordered to one year's active duty immediately on completion of their internship. The text of the communication of the Adjutant General reads:

SUBJECT: Deferment of Medical Students.

TO: All Corps Area and Department Commanders, and The Surgeon General.

1. Authority is granted for the commissioning as second lieutenants in the Medical Administrative Corps Reserve, after July 1, 1941, male junior and senior medical students in grade A medical schools in the United States who are fit for military service; also for commissioning interns as first lieutenants, Medical Corps Reserve, with the understanding that they will be ordered to one year's active duty immediately on completion of their internship.

2. Appropriate publicity will be given the above authority by the Corps Area and Department Commanders. Students and interns who are properly qualified will be invited to submit applications for appointment, final approval in each case to be made by the War Department.

By order of the Secretary of War:

E. A. ADAMS,
Major General,
The Adjutant General.

On June 18, 1941 these orders were further amplified by authority to transfer officers so appointed to the War Department Reserve Pool and retained therein until eligible for appointment in the Medical Corps Reserve. The letter from the War Department outlining the procedure to be followed in applying for commissions has been forwarded to the dean of every medical school. The letter is as follows:

SUBJECT: Appointment of Medical Students in the Medical Administrative Corps Reserve.

TO: All Corps Areas, Department Commanders, and The Surgeon General.

1. The letter of this office of May 26, 1941 (AG 210.1 Med-Res. 5-1-41 RB-A) Subject: Deferment of Medical Students, is rescinded, and this letter is substituted therefor.

2. Authority is granted to Corps Area Commanders to waive the provisions of paragraph 5, Army Regulations 140-33, for the appointment in the lowest grade in the Medical Administrative Corps Reserve, after July 1, 1941, of physically qualified male citizens who are bona fide matriculants at approved medical

schools within the United States and who have successfully completed the first two years of their medical education. Officers so appointed will be transferred to the War Department Reserve Pool and retained therein until eligible for appointment in the Medical Corps Reserve, or for action under paragraph 3 (c) below.

3. (a) Appointment will be made without reference to an examining board as prescribed in paragraph 20 c, AR 140-5, and without reference to the peacetime procurement objective for the Medical Administrative Corps Reserve.

(b) Applications, accompanied by report of physical examination, will be forwarded by the dean of the medical school to the commanding general of the corps area in which the school is located, together with a certified statement that the applicant has successfully completed the freshman and sophomore years of medical instruction and is an accredited matriculant in the junior or senior class in medicine at the institution. The certificate will state the prospective date of completion of the prescribed four year course of medical instruction.

(c) Officers of the Medical Administrative Corps Reserve appointed under the provisions of this letter and transferred to the War Department Reserve Pool will be discharged from the Officers' Reserve Corps for the convenience of the government, under the following circumstances:

1. Discontinuance of medical education.
2. Matriculation in an unapproved school of medicine.
3. Failure to complete successfully the prescribed four year course of medical instruction.
4. Failure to secure appointment in the Medical Corps Reserve within one year of the completion of the prescribed four year course of medical instruction.

(d) The Surgeon General will maintain adequate records to assure timely application for appointment in the Medical Corps Reserve and transfer from the War Department Reserve Pool, and to assure discharge as provided above.

4. Transfer to the Medical Administrative Corps Reserve of Reserve officers of other branches who are studying medicine, dentistry and veterinary medicine as authorized in AG letters dated April 17 and Aug. 28, 1940, Subject: Special Mobilization Procedures for Procurement of Medical Department Reserve Officers who are Students in Approved Medical Schools (AG 210.31 ORC 10-24-39 R-A) will continue as now authorized. Such transfer may be effected prior to actual matriculation provided the applicant has been accepted for enrolment by an approved school.

5. Appropriate publicity will be given the above authority by Corps Area Commanders, Department Commanders and the Surgeon General. Properly qualified students will be invited to submit application for appointment, final approval in each case to be made by the War Department.

By order of the Secretary of War:

E. A. ADAMS,
Major General,
The Adjutant General.

It would appear that every effort is being made by medical educators to cooperate in the national emergency while at the same time endeavoring to insure that the education of physicians is continued at the present level and without interruption. It should not be necessary to argue that a continuing and undiminished supply of well trained physicians is absolutely essential to the welfare of the nation. We cannot speed up that training beyond a certain point without lowering educational standards and degrading the quality of medical service. The present crisis demands, in fact, better qualified physicians if we are to face the future with reasonable confidence. Those who represent the medical schools are making every effort to preserve their institutions and to maintain, unimpaired, their priceless contribution to the health and welfare of the nation.

DEVELOPMENTS IN MEDICAL EDUCATION

The objective of medical education, it is customarily assumed, is the development of the best practitioners of medicine. Integrity, intelligence, industry, judgment and skill in the use of the scientific method are recognized as necessary traits of the successful medical student, to whose growth and development the school of medicine may largely contribute. The leading schools strive to bring out the best that is in each student by making him largely responsible for his own education.

Students applying for admission to medical schools are selected on the basis of the qualities enumerated, so far as they can be evaluated, and on evidence of capacity for intellectual growth, self reliance and maturity, all of which have little relationship to age or subjects taken. The subjects in which every medical student needs basic knowledge are English, physics, chemistry and biology. They provide him with a means of expression and a foundation for further study in the medical sciences. The Council's minimum requirement for admission to medical schools since 1918 has been two years of college work, including courses in English, and theoretical and practical courses in physics, biology and general and organic chemistry. Since 1939, three years of college study has been recommended for entrance into medical school. At that time 3.8 per cent of all students were admitted to nineteen schools with the minimum of two years. For the session 1940-1941 only eighty-three students, 1.4 per cent, were accepted by nine schools.

One of the striking chapters in the history of education deals with the part played by the American Medical Association, through its Council on Medical Education and Hospitals, in raising the standards of medical education in the United States. Instead of the poorest medical schools in the world, we now have the best. If the public had had to wait until a popular majority interested itself in providing good medical schools, we should have few of these schools today. It was the understanding of the physician together with his willingness to take responsibility and to contribute of his time and means that has made possible the unparalleled transformation of the last thirty years in the field of medical education. There has been a steady improvement in medical schools, in hospitals and, above all, in the competence of the young physicians who are entering practice.

During the academic years 1934-1936 a resurvey was made of all medical schools in the United States and Canada. The Council received the assistance and cooperation of the Association of American Medical Colleges and of the Federation of State Medical Boards of the United States. Representatives of the Council, in company with a representative of the college association or of the medical boards, visited eighty-nine schools in the United States and Canada. The results of this study were published early in 1940¹ and contained an analysis of a vast amount of data supplied voluntarily by the schools. Although there were wide variations in the excellence of the schools visited, even the weakest of them was a stable and reputable institution as compared with the proprietary schools and diploma mills which existed before the Council on Medical Education and Hospitals began its investigations. The Council therefore refrained from publishing an individual analysis and criticism of each school but instead described

in general terms the organization and administration, faculty and student personnel, and the clinical and financial resources of the schools, endeavoring to present an objective picture of medical education in this country for the years under review. However, to each school was sent a confidential report, showing graphically how it compared with the other recognized schools. By this analysis immediately many weaker schools were stimulated to bring themselves up to a higher standard. To some, even of the leading schools, it revealed deficiencies that had gone unnoticed. Universities have evinced greater interest in their medical departments, attempts have been made to develop new hospital relationships, and faculties of medicine have manifested more intense and personal interest in the improvement of their institutions.

Since the first classification of medical schools and the publication of the Carnegie report, probably no period has witnessed such activity and progress in the field of medical education as the last six years.

TABLE 1.—Improvements in Medical Schools in the United States, 1940-1941

Budgets	10 schools increased annual budgets from \$5,000 to 33 per cent
Selection of students	Students selected more carefully, entrance requirements raised, higher scholastic standards adopted
Instructors	Additional instructors added in both laboratory and clinical divisions
Preclinical facilities .	New laboratory building opened or ambitious building programs under way by four schools
Clinical facilities....	New hospital building erected, wings added or buildings remodeled, affiliations reported, increase in beds allotted to teaching, better control of hospital facilities and better working arrangements reported by eight schools
Curriculum	Curriculum of junior and senior years extended through summer months to take full advantage of available clinical material reported by four schools
Library	The libraries of three schools have been improved by the addition of a new building, purchase of additional books and periodicals or a grant
Other facilities....	(a) Orientation of laboratory work with the main branches of clinical work by two schools (b) Two schools report that teaching facilities in the field of psychiatry have been strengthened

A number of other innovations have been added designed to increase the practical value of the medical school training.

Summing up the reports of activities of the medical schools during the academic year 1940-1941, it is gratifying to outline the substantial improvements presented in table 1.

Medical schools now face an entirely new set of conditions. In the existing emergency, various pressure groups threaten to destroy or seriously impair the achievements of the last generation. At the same time, in the defense program, 617 instructors, chiefly Medical Reserve Officers, have gone to the colors. Their duties have been assumed, in many cases, by men of less experience. In many instances hospitals and medical schools have been cooperating actively with local, appeal, medical advisory and induction boards of the Selective Service by making available their facilities, resources and personnel. Many schools have organized hospital units. In the midst of all these activities every effort must be made to maintain our present standards in the training of physicians so that the health of our people shall not suffer.

PRELIMINARY EDUCATION

Since 1915 the Council on Medical Education and Hospitals of the American Medical Association has published a list of approved colleges of arts and sciences

Statistics of Recognized Schools of the Basic Medical Sciences will be found in table 5, page 589.

* On probation since Dec. 4, 1938.

† Enrollment not on above table by classes for the two medical schools of the University of Chicago.

‡ Fifth year (internship) enrollment not included in total column.

§ Fifth year (internship) discontinued beginning with the class of 1941 because of the national emergency.

|| Fifth year (internship) discontinued for class of 1941 because of the national emergency.

†† Two year internship required after graduation.

‡ Sixth year enrollment: Alberta, 38; Queen's, 44; Western Ontario, 31; Toronto, 130.

(Continued from page 685)

as a guide to medical schools in the selection of students and also to assist the prospective medical student in choosing a college for his premedical training. This list comprises colleges approved by the following national and regional educational associations:

- Association of American Universities.
- North Central Association of Colleges and Secondary Schools.
- Middle States Association of Colleges and Secondary Schools.
- New England Association of Colleges and Secondary Schools.
- Southern Association of Colleges and Secondary Schools.
- Northwest Association of Secondary and Higher Schools.

There are seven hundred and one colleges of arts and sciences approved by these agencies distributed as follows:

Association of American Universities.....	304
North Central	253
Southern	200
Middle states	128
Northwest	60
New England	44

Of those recognized by the Association of American Universities, all but nineteen are approved also by their district agency. In the various groups this dual approval of two hundred and eighty-five institutions is apportioned as follows:

North Central	109
Middle states	66
Southern	61
New England	31
Northwest	18

The five regional associations of colleges referred to cover among them the entire United States with the exception of the Far Southwest. Institutions in this area can secure only the approval of the national group—the Association of American Universities.

Junior colleges are approved by these agencies but are omitted from the Council's compilation. This action was taken Dec. 10, 1939 because the Council itself recommends three years of college preliminary to entrance into medical school and because all but a negligible percentage of medical students have actually taken three years or more in college. Medical schools, therefore, are selecting their students from among those who are already enrolled in colleges of arts and sciences which offer the full four year course leading to a bachelors' degree.

TABLE 3.—Requirements for Admission to Medical Schools, 1936-1941

	Degree	Years				
		Four	Three*	Three	Two and One-Half	Two
1936-1937.....	4	1	3	26	1	22
1937-1938.....	5	1	4	29	1	27
1938-1939.....	5	1	5	45	2	19
1939-1940.....	5	1	5	55	..	11
1940-1941.....	6	1	5	56	..	9
1941-1942.....	5	1	5	58	..	8

* Baccalaureate degree conferred in absentia at end of first medical year

While the minimum requirement of collegiate credit advocated by the Council is two years of college training, which include English and theoretical and practical courses in physics, biology and general and organic chemistry, three years or more in college is recommended. Since it cannot in general be assumed that all who have satisfied these requirements in terms of

hourly credits are fitted for the study of medicine, qualitative standards also are imposed. As a rule applicants receive their preliminary education in institutions approved by accrediting agencies. Exception, however, is made in the case of those students who demonstrate superior ability.

TABLE 4.—Freshman Students Admitted with Less than Three Years of College Preparation

	Number of Schools With Two Year Requirement	Percentage
1936-1937.....	32	12.5
1937-1938.....	27	7.4
1938-1939.....	10	3.8
1939-1940.....	11	2.0
1940-1941.....	9	1.4

For the session 1941-1942, sixty-nine of the seventy-seven medical schools in the United States have adopted preliminary requirements in excess of the minimum; i. e., five require a degree, fifty-eight require three years, one requires four years and five schools will admit students with three years of college work if the baccalaureate degree is conferred in absentia at the end of the first year in medicine. Only eight schools have a stated two year requirement. These schools are the Universities of Arkansas, George Washington, Howard, Louisville, Harvard, Buffalo, Pittsburgh and Tennessee. In table 3 are presented for six years figures indicating the trend toward increasing admission requirements. The College of Medical Evangelists increased its prerequisite for the forthcoming session to three years. Albany Medical College, for the duration of the national emergency, has reduced its preliminary requirement from a degree to three years of college.

The general trend toward three or more years of college work would appear to be due to a desire for more thorough grounding in all the branches of chemistry and greater familiarity with nonscience subjects, such as languages, literature, history or economics. In table 4 it will be noted that actually but 1.4 per cent of the entire freshman class of 1940-1941 was admitted with less than three years. Of the nine schools with a two year requirement for this session, three admitted none on this basis, one admitted five, another eleven, two accepted thirteen, while one accepted twenty and still another twenty-one, a total of eighty-three. Thus eighty-three students were enrolled in six schools with two years of college work, although in each case they represent less than 50 per cent of the freshman class. In 1936-1937, 12.5 per cent of the entering class had only the minimum of preliminary education, but by 1938-1939 the number dropped to 3.8 per cent and in 1940-1941 to 1.4 per cent.

The importance of careful selection of students of medicine cannot be overstated. No other element in medical education is so significant for the future. Schools of medicine are in a fortunate position as compared with other professional schools in that they receive annually applications from more than twice as many candidates as they can accept. Entrance requirements have been progressively raised, but the mere accumulation of college credits is no guaranty of fitness for the practice of medicine.

The faculties of medicine in Canada vary in their premedical requirement. For the session 1940-1941 two required a degree for admission to a five year course, two had a six year medical course preceded by senior

matriculation which is equivalent to the work of the first year in a college of arts, five, including one school offering courses in the basic sciences, required two years, and one school requires three years before beginning a four year course. A table appears later in this study which records the number of graduates of 1941 holding baccalaureate degrees (table 21).

With but five exceptions, namely California, Connecticut, Massachusetts, Missouri and Nebraska, the state licensing boards also exact the two year requirement. Although their statutes do not conform with the two year college prerequisite, these states, with the exception of Massachusetts, do not license other than graduates of approved schools. Table 6 records the preliminary training required by each state medical licensing board. Alaska, Hawaii and Puerto Rico likewise require two years of preliminary training.

LENGTH OF MEDICAL COURSE

In fifty-two medical schools in the United States the medical course is taught in four calendar years of approximately thirty-two weeks. Seven medical schools,

Rush Medical College has heretofore offered clinical courses but will discontinue undergraduate teaching with the class of 1942.

Ten schools in the United States and one in Canada offer only the first two years of the medical curriculum and are designated as schools of the basic medical sciences.

The majority of these schools are located in smaller communities where the material required for clinical teaching is almost wholly lacking. In some instances, facilities for the satisfactory teaching of such subjects as physical diagnosis and gross pathology must be sought at a distance from the school. Introductory courses in medicine and surgery, which commonly form a part of the second year schedule, may be similarly handicapped. A study of the problem by the Council on Medical Education and Hospitals led to the adoption on July 1, 1939 of approving these institutions as schools of the basic medical sciences. The Council in giving its approval to these schools assumes no responsibility for the character of those courses which involve the use of clinical material.

* On probation since May 13, 1939.

by eliminating long summer vacations, make possible completion of the course in less than forty-four consecutive months (table 7). A considerable number of the students of these schools do not elect to study during the summer months. The medical schools of the University of Chicago are operated on a plan of individual promotion permitting a student to advance as rapidly as he desires, but the great majority complete the course in twelve quarters. Medical practice acts of certain states, however, specify a four year professional course and it is advisable that students should assure themselves concerning the legal interpretation of the phrase.

Fifty-two schools offer a four year course; seven have a continuous schedule, four of which also require a hospital internship; seven require four years of systematic instruction followed by a fifth year spent as an intern or in research work. In all, there are sixty-six schools which offer the complete medical course.

Because of the existing national emergency, special sessions for senior medical students have been arranged in eleven schools to make possible completion of the course at an earlier date. These schools are named in table 8, together with data as to whether the schedule is required or optional, the date when these classes began, when they will end, and the date of graduation.

Four of the medical schools of Canada offer a five year course, four have a six year course, one offers four years and there is one school of the basic medical sciences. Three Canadian schools require an internship for graduation.

CURRICULUM

The standard curriculum recognized by the Council on Medical Education and Hospitals and contained in its Essentials of an Acceptable Medical School consists of from three thousand six hundred to four thousand

four hundred distributed as from nine hundred to one thousand hours a year and grouped under nine headings: anatomy, including histology and embryology; physiology; biochemistry; pathology, bacteriology and immunology; pharmacology; hygiene and sanitation; general medicine; general surgery, and obstetrics and

gynecology. A certain percentage of hours of the whole number of hours in the courses is required in each of these groups.

APPROVAL OF SCHOOLS IN CANADA

At a meeting in Ottawa, Ont., in 1937, at which representatives of the medical schools in Canada and the assistant secretary of the Canadian Medical Association were present, the secretary speaking for the Council on Medical Education and Hospitals discussed the survey of Canadian medical schools made during 1934-1936 and inquired as to the policy to be adopted in the future; that is, whether the American Medical Association should continue the grading of medical schools in Canada or whether they would prefer that the medical schools themselves or some other body take over this task. The problem was referred to the Canadian Medical Association. At its sixty-ninth annual meeting in June 1938 the Committee on Medical Education of the Canadian Medical Association brought in a report which was accepted by the members of the General Council of the Canadian Medical Association and reads, in part, as follows:

In the event of the Council on Medical Education of the American Medical Association publishing a list of approved schools, those Canadian schools wishing their inspection and approval could request this inspection. This would leave each school free to deal directly with the Council on Medical Education of the American Medical Association and thus obviate misunderstandings. There seems to be a fairly uniform opinion expressed by the various medical schools in Canada that the Canadian Medical Association should share some responsibility in this country so far as medical education is concerned. The majority of the schools, however, feel that the aims and purposes of the Canadian Medical Association are not primarily those of undergraduate medical education, which is largely a problem of the schools themselves. However, it was recommended that, if the Council on Medical Education and Hospitals of the American Medical Association in the future conduct similar surveys at five or ten year intervals, such as the recent survey, the Canadian schools take advantage of and be included in this survey. Those schools which are members of the Association of American Medical Colleges could have a representative from

this association included in the personnel of the inspection. The remaining schools which are not members of the Association of American Medical Colleges could ask to have a member of the Association of American Medical Colleges included in the inspecting personnel, or some representative from the Committee on Medical Education of the Canadian Medical Association.

It would appear from the foregoing that the approval of Canadian medical schools by the Council on Medical Education and Hospitals of the American Medical Association rests with the schools themselves. The Council on Medical Education and Hospitals at a meeting in St. Louis on May 13, 1939 voted that after Jan. 1, 1945 the Canadian medical schools will be included in the Council's classification only at their request.

MEDICAL SCHOOLS AND SCHOOLS OF THE BASIC MEDICAL SCIENCES

Medical schools and schools of the basic medical sciences approved by the Council on Medical Education and Hospitals during 1940-1941 are listed in tables 2 and 5, pages 686-687 and 689. In addition to the name and location of the schools there is recorded the preliminary college requirement for the coming session, the enrolment by classes during 1940-1941, including figures indicating the number of fifth year students interning or engaged in research, the total attendance, the number of graduates receiving the degree of Doctor of Medicine since July 1, 1940, the month until which applications for admission to the freshman class are received and the name of the dean or executive officer. Three schools on probation are indicated by an asterisk. Figures for the sixth year enrolment in Canadian schools are given in a footnote. The fifth year (internship) enrolment is not included in the column giving the total number of students by classes. Two schools discontinued the internship requirement affecting the class of 1941, i. e. the University of Cincinnati College of Medicine, where it has been permanently dropped, and the University of Illinois College of Medicine. At the latter school, because of the national emergency, the requirement was waived for those completing the senior year in 1941. The University of Cincinnati awarded degrees to 75 students who completed the course in 1940 and served internships during 1940-1941, and to 76 who completed

University of Texas.....

* Plans indefinite.

four years work in 1941. The University of Illinois granted degrees to 164 students who completed the course in 1940 and served internships and to 138 who finished their four years of study in 1941. Duke University School of Medicine requires a two year internship after graduation, but one year of Army or Navy medical service is accepted in lieu of the second year of the internship. The two medical schools of the

University of Chicago do not report their students by classes, and in this tabulation, therefore, only the total enrolment is given.

The data presented in these tables constitute the basis also for several of the subsequent tabulations. Beginning on page 701 are given historical information and essential facts concerning the schools arranged by states.

‡ Will graduate with regular class in June.

Sixty-seven medical schools in the United States and nine faculties of medicine in Canada are listed in table 3, and ten schools of the basic medical sciences in the United States and one in Canada in table 5. All but three of these schools at the present time have the approval of the Council; the three on probation being the University of Arkansas School of Medicine since Dec. 4, 1938 and the medical schools of the universities of North Dakota and South Dakota since May 13, 1939.

The freshman enrolment in eighty-five medical schools of the United States and Canada (excluding the schools of the University of Chicago, which do not report by classes) for the session 1940-1941 was 6,452, sophomores 5,847, juniors 5,485, seniors 5,360, fifth and sixth year students 299 and 248, respectively. In the two medical schools of the University of Chicago 470 students were enrolled, making a total of 24,161 in the eighty-seven schools listed.

In the United States there were 5,837 freshmen, 5,254 sophomores, 4,969 juniors, 4,849 seniors and the 470 students of the University of Chicago, a total of 21,379 students enrolled in seventy-seven schools. The number of students studying medicine in the United States, including fifth or intern year students, was 22,437. The enrolment in the schools of the basic medical sciences in the United States numbered 615, of which 331 were freshmen and 284 sophomores.

The enrolment in the ten Canadian faculties of medicine included first year 615, second 593, third 516, fourth 511, fifth 299, and sixth year 248, a total of 2,782. In the one school of the basic medical sciences in Canada there were 49 students: 24 freshmen and 25 sophomores.

Students enrolled in institutions in the United States and Canada and working for the degree of Doctor of Medicine numbered 24,161, exclusive of 1,058 fifth year students in the United States interning or engaged in research and 156 Canadian students serving internships. In addition there were 132 part time and 299 special students and 1,167 others studying in medical schools.

The degree of Doctor of Medicine since July 1, 1940 has been awarded to 5,837 students; 5,275 received the

degree from medical schools in the United States and 562 from Canadian faculties of medicine.

The schools of the basic medical sciences, with one exception, had an enrolment of less than 100. The lowest enrolment among the schools offering the complete course was 115 students at the Woman's Medical College of Pennsylvania and the highest 747 at the University of Toronto Faculty of Medicine. The high figure among schools in the United States was 616 at the University of Illinois College of Medicine.

Eight schools in the United States, exclusive of those of the basic medical sciences, matriculated less than 200 students, thirty-one between 201 and 300, thirteen from 301 to 400, ten from 401 to 500, and four from 501 to 600. One school matriculated more than 600. Among Canadian schools offering the entire medical course, one had an enrolment of less than 200, five between 201 and 300, two from 301 to 400 and one over 700. The smallest enrolment (41) was at Dartmouth Medical School, where 23 freshman and 18 sophomores were enrolled. This school does not offer the complete medical course.

Howard University College of Medicine graduated 22 students, the lowest number; Woman's Medical College of Pennsylvania, which had the lowest enrolment, 23 graduates. In the United States the University of Illinois College of Medicine granted the greatest number of degrees (302). This figure represents a double graduating class, since, because of the existing emergency, the internship was waived for the senior class of 1940-1941, representing 138 students. Fourteen schools granted degrees to classes of fewer than 50 students, thirty-eight graduated between 51 and 100 each, thirteen between 101 and 150, one between 151 and 200, and another more than 300. In Canada one school graduated more than a hundred students, while in four schools each there were between 51 and 100 graduates and also fewer than 50.

Of fifty-seven schools that replied to the inquiry regarding the month until which applications for admission to the first year class will be received, eighteen replied March, nine September, five each January, May, June and August, four each April and July, and two February.

BIRTHPLACE OF STUDENTS

In table 9 the birthplace of medical students of the United States and Canada in attendance during 1940-1941 is shown by schools. The state furnishing the greatest number of students, according to state of birth, was New York with 2,686, followed by Pennsylvania with 1,880, Illinois with 1,309 and Ohio with 1,085. Every state and the District of Columbia is represented in this table. From each of four states there was a student enrolment of between 701 and 1,000, and between 501 and 700, from five states 401 to 500, from seven states between 301 and 400, from nine states each 201 to 300 and 101 to 200, and from seven states less than 100. There were 208 born in the United States territories and possessions studying in fifty schools in the United States and two in Canada. In addition, 2,511 students of Canadian birth were also studying medicine, 127 of whom matriculated in forty-five schools in the United States and 2,384 in ten Canadian medical schools. Eighteen students of Canadian birth were registered at the College of Medical Evangelists, 10 at Wayne University College of Medicine and 7 at the University of Oregon Medical School. All other schools registered fewer than 7.

(Continued on page 694)

of Students

[illegible]

(Continued from Page 691)

Students born in New York were enrolled in all but ten schools and in every state with the exception of Mississippi, North Dakota, Oregon, South Dakota, Utah and West Virginia. Students from New York were registered in two of the six provinces of Canada having medical schools. None were studying in Alberta, Manitoba, Nova Scotia or Saskatchewan. Pennsylvania was represented in all but eleven states and four provinces.

There were 729 students born in New Jersey, which has no medical school, admitted to sixty-three schools, while 321 from the state of Washington, which likewise has no medical school, enrolled in forty-eight schools. From the twelve states in which no medical schools are located there were 1,892 students in at least sixty-three schools as follows:

	Enrolled	No of Schools
Arizona	47	29
Delaware	36	17
Florida	187	38
Idaho	112	35
Maine	113	34
Montana	125	38

Total	57	15,650	10,002

so enrolled, 456 in the United States and 167 in Canada. Thirty were so registered at New York University College of Medicine, 28 at Harvard Medical School and 26 at the College of Medical Evangelists. Other schools registered fewer than 16. It may be presumed

that many of these students are now citizens of the United States.

The medical school enrolment is further classified by birthplace in table 10. This compilation reveals that 13,659 students are studying in the state of their birth and 10,502 elsewhere. This is particularly significant in Illinois, where, of the 1,912 students enrolled in five schools, 995 were born outside the state. More than 950 born outside the state were enrolled in institutions in New York and Pennsylvania, but the number of those born within and studying in these states was greater. Schools located in California, Connecticut, the District of Columbia, Kentucky, Louisiana, Maryland, Massachusetts, Missouri, New Hampshire, North Carolina, Oregon, South Dakota and Tennessee enrolled more students from outside the state than from within.

In the United States 11,275 students were attending school in the state of their birth and 9,104, 45 per cent, elsewhere. Eliminating the 1,892 students from states which have no medical school, there are still 7,212 students who, though born in a state which had a medical school, are studying elsewhere.

While a perusal of table 10 will show many instances wherein the number studying elsewhere far exceeds the number attending school in the state of birth, it also shows some states in which the contrary is the case, notably Arkansas, Georgia, Indiana, Iowa, Minnesota, Ohio, South Carolina and Texas.

In Canada 398 of the 2,782 students were born outside the dominion.

It should not be inferred that every medical student enrolled in a state other than that of his birth is still a resident of his natal state. Still less should it be assumed that every one of these students has become a legal resident of the state in which his professional studies are pursued.

RESIDENT AND NONRESIDENT STUDENTS

Table 11 gives for each medical school in the United States the number of resident and nonresident students according to the individual school's definition of the word "resident." There is a wide variation in the definition of this term among both state universities and other schools. In some universities this is determined by the legal or permanent residence of the student, parents or guardian only, while in some schools continuous residence for from six months to one, two or three years just prior to the student's application for enrolment is also required. Other schools require the student to be a voter; that the parents' home in the state be established prior to the beginning of premedical work; the student to be a taxpayer or a dependent of a taxpayer, regardless of whether he resides in the state, while other schools require the student to be self-supporting. In a few schools each case is determined by an attorney after consideration of birth, citizenship, residence of parents and so on. Most commonly residence is determined by ascertaining whether the student's parents or guardian has been a bona fide resident for a period of not less than six months. Among medical schools of other than state universities a residence is defined for the most part by the home address of the student or the legal residence of the parents or guardian.

The sixty-seven approved medical schools and the ten approved schools of the basic medical sciences reported 13,278 resident and 8,101 nonresident students. The state university enrolling the greatest number of nonresidents was the University of Tennessee College

of Medicine, which had 218 resident and 243 non-resident students, while at the Universities of Georgia, Illinois, Missouri and West Virginia nonresidents were not registered.

Among other than state universities, it will be noted, there are many schools which select their students from

Totals	13,278	8,101	21,379

academic year 1936-1937, are shown in table 12. The figures do not vary to any measurable extent.

The ten faculties of medicine of Canada, including one offering courses in the basic medical sciences, reported 1,890 residents and 892 nonresident students. The definition of a resident by these schools varied from students whose permanent address is within one of the provinces of Canada, or the specific province in which the school is located, to home address on registration and taxpayers. The greatest number of nonresidents in any one school was reported by McGill University Faculty of Medicine. This school obtains a large portion of its student body from the United States.

The figures in tables 11 and 12 giving the number of residents and nonresidents and the preceding one classifying students by birthplace shows a divergence. More than 1,000 students born outside the state have been classified as residents. Excluding Canadian registration given in tables 9 and 10, there were 11,275 attending school in the state of their birth and 9,104

TABLE 12.—Resident and Nonresident Students, 1936-1940

	Resident	Nonresident	Totals
1936-1937	14,026	8,060	22,086
1937-1938	13,518	8,069	21,587
1938-1939	13,418	7,884	21,302
1939-1940	13,292	7,970	21,262
1940-1941	13,278	8,101	21,379

elsewhere, as compared with 13,278 whose legal residence is in the state in which they are pursuing their medical courses and 8,101 classified as nonresidents.

Comparing the figures for Canada in table 10 reveals somewhat similar results: 2,384 born in Canada and 398 elsewhere, while there were 1,890 residents and 892 nonresidents.

SCHOOLS, STUDENTS AND GRADUATES BY STATES

The number of schools, students and graduates by states are shown in table 13. Medical schools are located in thirty-six states and the District of Columbia. New York, with the largest number of schools, nine, had the greatest number of students (2,646) and 617 graduates, respectively. Pennsylvania with six schools had 2,379 students and 565 graduates; Illinois with five schools 1,912 students and 679 graduates ranks third, while Massachusetts with three schools, 1,107 students and 260 graduates completes the group of states having an enrolment of more than 1,000, although California had just under 1,000 students, 978 students and 253 graduates respectively.

In the seventy-seven schools, including those that offer courses in the basic medical sciences only, there were 21,379 students and 5,275 graduates. Students interning as a requirement for the degree, fifth year students, are not included in this tabulation. Neither are part time, special or other students pursuing courses in medical schools not leading to the M.D. degree.

The greatest number of graduates in any one state was 679 who completed their course in Illinois. There were 617 from New York schools and 565 from schools in Pennsylvania. Four other states had more than 200 graduates—California, Massachusetts, Ohio and Tennessee. Ten states had more than 100 but less than 200 graduates. Seven states had no graduates, as the medical schools located therein do not offer the complete medical course. All others had less than 100, the lowest being 31 who received their degrees from the one medical school in Vermont.

among the residents of the state. This is particularly significant at the Universities of Southern California, Stanford, Tufts, Long Island and Baylor. The enrolment in municipally controlled medical schools consisted largely of resident students.

Figures indicating enrolment of resident and non-resident students for five years, beginning with the

The status of two medical schools will change in the future.

Undergraduate courses at Rush Medical College will terminate in June 1942, when the students now enrolled will complete their courses. For the session 1941-1942

* Excluding fifth or intern year students

only senior students will be enrolled. Rush Medical College has formed an affiliation with the University of Illinois, and its clinical facilities will after June 1942 be available to the university for purposes of graduate and undergraduate instruction.

On Aug. 4, 1939 the board of trustees of Wake Forest College accepted the resources of the Bowman Gray Foundation in Winston-Salem. The medical school of Wake Forest College was moved to Winston-Salem in the summer of 1941 and will be known as the Bowman-Gray School of Medicine of Wake Forest College. The school is planning to offer a complete medical course beginning with the session 1942-1943.

REQUIRED INTERNSHIPS

In tables 14 and 15 are listed the medical schools and state licensing boards now requiring internships for the M.D. degree and state licensure respectively.

Eleven schools in the United States and three in Canada require an internship for graduation. Several medical schools will accept research or other clinical work in lieu of hospital service. The University of Minnesota Medical School in 1915 was the first school to adopt the internship as a basis for the M.D. degree. The two medical schools of the University of Chicago, i. e. Rush Medical College and The School of Medicine, discontinued this formal requirement in 1936, and Louisiana State University School of Medicine in 1940. During 1941 this requirement was dropped by the University of Cincinnati School of Medicine, affecting the senior class of 1941. At the University of Illinois College of Medicine the internship requisite was waived for the senior class of 1941 because of the national

emergency. The two schools last named awarded 151 and 302 M.D. degrees, respectively, to the group who interned during the last academic session and to those who completed only the four year medical course during this period. The fifth year was also discontinued by McGill University Faculty of Medicine as a result of the reorganization of its medical curriculum affecting the freshman class of 1936-1937. The M.D. degree is conferred by this school on completion of four sessions of thirty-six teaching weeks, but the holders of these degrees are not eligible for the licensing examination in Quebec until the completion of a hospital internship. The M.D. degree is likewise conferred by Duke University School of Medicine after completion of the senior year, but all graduates are required to spend at least two years in a hospital or laboratory work after graduation. This school will now accept one year of military service in lieu of the second year of internship. While this requisite has been dropped by four schools in the United States and one in Canada since 1936, a similar requirement has not been added to the qualifications for an M.D. degree by any school.

The medical licensing boards of twenty-one states, the District of Columbia, Alaska, Hawaii and Puerto Rico require that all applicants for licensure serve a hospital internship. The first state exacting this requirement was Pennsylvania in 1914. Some states require the internship of graduates of medical faculties abroad and of applicants for reciprocity or endorsement.

Some of the medical schools and licensing boards have their own list of hospitals acceptable for intern training, but the list of hospitals approved for intern training by the Council on Medical Education and

Hospitals is generally in use. A revised edition of the Council's list will be found beginning on page 757.

There were 1,058 students in the United States and 156 in Canada, a total of 1,214, reported as completing the fifth or intern year requirement of the medical schools which exact the fulfillment of the internship as

a requisite for the M.D. degree. Statistics computed indicate that 98 per cent of the graduates of recent years have obtained or are obtaining this added experience.

DISTRIBUTION BY SEX

Students and graduates in the United States distributed by sex are given in table 16. Seventy-six schools had both men and women students, of which

sixty-six had women graduates. Of this total, nine Canadian faculties had students of both sexes and four had both men and women graduates. Women were enrolled in six of the ten schools in the United States offering courses of the basic medical sciences and also in the one such school located in Canada.

Male students numbered 22,853 and included 5,527 graduates; the number of female students 1,308 and graduates 310. In the United States there were 20,233 male students and 4,995 graduates, and in Canada 2,620 students and 532 graduates. Likewise there were 1,146 women students and 280 graduates in the United States and 162 women students and 30 graduates in Canada.

There were 2,924 students and 655 graduates enrolled in schools which are not coeducational. Included in these figures are 266 students and 42 graduates of one school in Canada.

In the one medical school for women, 115 students were enrolled and 23 graduates.

An average of 16 women students were enrolled in the sixty-eight coeducational institutions, and an average of 3 graduated from each of fifty-nine schools. The greatest number of women enrolled in coeducational institutions in the United States was 38 each studying at the University of Illinois, New York University and Temple University, while in Canada the University of Toronto enrolled 59.

TABLE 17.—*Distribution by Sex in the United States and Canada, 1936-1940*

Year	Students		Graduates	
	Male	Female	Male	Female
1935-1936.....	24,219	1,254	5,388	269
1936-1937.....	23,767	1,244	5,024	261
1937-1938.....	23,234	1,307	5,439	252
1938-1939.....	22,919	1,293	5,290	285
1939-1940.....	22,903	1,291	5,430	273
1940-1941.....	22,853	1,308	5,527	310

Figures are given in table 17 showing this distribution for a six year period. While the total number of male students has been slightly decreasing, the figures show a slight increase in women medical students.

WOMEN IN MEDICINE

The first woman to receive the degree of Doctor of Medicine in the United States was Elizabeth Blackwell. She studied in and graduated from the Geneva Medical College at Syracuse, N. Y., in 1849. The first medical school for women, the Woman's Medical College of Pennsylvania, was organized in 1850 with a class of seven. It is still functioning and is said to be the only medical school exclusively for women.

During the past year, as shown in table 18, there were 1,146 women studying medicine, constituting 5.4 per cent of the total student enrollment. Twenty-seven more women were graduated than in 1940. They numbered 280, or 5.3 per cent. Of the women matriculants, 115 were in attendance at the one medical school for women while 1,031 were matriculated in sixty-eight other schools. Twenty-three were graduates of the Woman's Medical College of Pennsylvania, while 257 secured their degrees from coeducational schools. In the seventeen years since 1925, 3,801 have received degrees in medicine. Statistics compiled from the American Medical Directory revealed that in 1940 there were 7,470 women physicians in the United States listed.

Women are admitted to all medical schools of the United States except Georgetown University School of Medicine, Emory University School of Medicine, Harvard Medical School, St. Louis University School of Medicine, Dartmouth Medical School and Jefferson Medical College.

The two schools which have been coeducational since their organization had no women students, namely the Universities of North and South Dakota.

The Hahnemann Medical College of Pennsylvania, which has never admitted women as students, will accept them for the next session.

PART TIME, SPECIAL AND OTHER STUDENTS
ENROLLED IN MEDICAL SCHOOLS

In forty-two medical schools in the United States and five in Canada, during the session 1940-1941, there were 1,598 part time, special and other students pursuing medical subjects, which are summarized in table 19. This group comprises 132 part time, 299 special and 1,167 others.

The students studying part time were enrolled in twenty-one schools in the United States and two in Canada. The largest group enrolled in any one school were 38 studying at the University of Kansas School of Medicine. Fourteen were registered at the University of Buffalo and 10 at the University of Pittsburgh. Less than 5 were enrolled in thirteen schools.

The 299 special students matriculated in twenty-eight schools in the United States and three in Canada. The greatest number (107) were at Northwestern University Medical School. At The School of Medicine of the University of Chicago 40 were in attendance, at the University of Texas 21, Columbia University and the University of Toronto each had 18 special students, while the University of Tennessee admitted 17. All other schools registered fewer than 10.

There were also 1,167 students not candidates for the medical degree pursuing medical subjects in eighteen medical schools of the United States and four in Canada. For the most part these students are enrolled in the graduate school. At New York University there were 245 such students and at the University of Illinois 225. Northwestern registered 138, the University of

SCHOOLS, STUDENTS AND GRADUATES, 1905-1941

The number of medical schools, students and graduates in the United States for five year intervals from 1905 to 1920 and for each year since is shown in table 20. In 1905 in the one hundred and sixty schools then

California 132 and Vanderbilt University 97, while other schools matriculated fewer than 55.

The University of Southern California, the University of Michigan, New York University and the University of Toronto matriculated all three of these types of students.

existing there were 26,147 students. The total number of undergraduate medical students for the college session 1940-1941 was 21,379, an increase of 108 over 1930-1940. This tabulation covers only candidates for the M.D. degree and does not include part time and special students, though their work may later be accepted as fulfilling part of the requirement for the M.D. degree.

In the ten years 1910 to 1920 there was a decrease in enrolment of more than 7,000, while from 1921 to 1935 there was a continuous increase. For four years the trend was slightly downward, and then in 1940 there was again an increase. This year it may be expected to increase still further, since some schools have announced a 10 per cent increase in the size of freshman classes because of the national emergency. Some schools also are planning slight increases in the enrolment of their advanced classes.

The number of graduates in 1941 was 5,275, an increase of 178 over 1940. The discontinuance of the internship requirement by two schools is responsible for the increase. The additional graduates numbered 214. There were, however, fewer graduates in 1941 from sixty-seven schools granting the M.D. degree than from 160 schools in 1905. With the exception of 1933, 1938 and 1939 there has been an increase in the number of medical graduates each year since 1925.

The decrease in student enrolment in 1936 and in the number of graduates in 1940 was in part the result of the survey of medical schools conducted by the Council on Medical Education and Hospitals during 1934-1936 and its recommendation to several medical schools that their enrolment be decreased in order to provide more adequate opportunities for the student body. There would have been a decrease in the graduating class of 1941 had not two schools discontinued their intern year.

Not shown in the table this year are figures for the year when the lowest number of M.D. degrees were granted. In that year (1922) there were only 2,520 graduates because of the small size of the class that entered as freshmen in 1918 during the World War.

1941.....	77	21,379	5,275

* Includes figures for schools of the basic medical sciences.

The number of medical schools in 1905 was one hundred and sixty; by 1910 the number dropped to one hundred and thirty-one and since 1915 there have been fewer than one hundred. Since 1933 there have been in the United States sixty-six approved four year schools, one offering only clinical courses, and ten schools of the basic medical sciences.

In the seventy-seven medical schools in the United States, including the schools of the basic medical sciences, there were 21,379 students and 5,275 graduates.

GRADUATES WITH BACCALAUREATE DEGREES

Table 21 records the number of graduates of medical schools in 1941 who held baccalaureate degrees. It will be noted that 3,647 of the 5,837 graduates held such degrees, while only five schools require a degree for admission. All the graduates of Stanford, Chicago, Wayne, Albany, Cornell, Western Reserve, Oregon, Jefferson and Vanderbilt—nine schools—held baccalaureate degrees. One of these schools has a degree requisite for admission, three will enroll students with three years of college training if the baccalaureate degree is conferred at the end of the first year in medicine, while four schools have a three year requirement. Four schools in the United States which have a degree requirement accepted altogether 9 students with less than the stated college education. None of the graduates of the University of Arkansas, the Medical Col-

lege of South Carolina or Dalhousie University were in possession of a college degree. The school in the United States having the fewest graduates with college degrees was Columbia University. Only 4 of the 104 graduates

had baccalaureate degrees. Of the 138 graduates of the University of Toronto, 29 were reported as having an arts degree. A percentage of 62.4 of all graduates held degrees.

GRADUATES WITH B.S. IN MEDICINE DEGREE

The graduates of twenty-six medical schools in the United States and two in Canada received the Bachelor of Science in Medicine degree. There were 577 awarded in the United States and 2 in Canada. The largest single

group to receive this degree were 103 graduates of the medical school of the University of Minnesota, while the University of Illinois issued 95 degrees. Other schools granted fewer than 50. In 1940 the graduates of thirty schools in the United States and two in Canada

TABLE 22.—Students in the United States by Years, 1930-1940

	Preclinical		Clinical		Intern Year	Total
1930-1931	6,456	5,528	5,080	4,908	1,025	23,007
1931-1932	6,320	5,462	4,932	4,855	1,067	23,202

* Excluding enrolment figures for the two medical schools of the University of Chicago, i. e., Rush Medical College 212 and The School of Medicine 258, a total of 470

awarded 738 such degrees, whereas in 1941 twenty-six schools in the United States and two in Canada granted 577 degrees. Fifty-eight graduates of Canada obtained the degree in 1940 and only 2 in 1941. Schools in general are discontinuing the practice of issuing such degrees, while others have never done so.

STUDENTS BY CLASSES, 1930-1940

The number of students enrolled in preclinical and clinical classes in the medical schools of the United States for each session from 1930 to 1940 is presented in table 22. For the session 1940-1941 the attendance for the first preclinical year was 5,837. In the second preclinical year 5,254 were registered. In the clinical years 4,969 and 4,849 respectively were enrolled. The two medical schools of the University of Chicago are not operated under the promotion by class system and therefore the figures for enrolment at these schools are included only in the total column. At Rush Medical College and The School of Medicine of the University of Chicago there were 470 students enrolled during the session just closed, 212 and 258 respectively.

By comparison, it will be noted that the freshman class was increased by 243, the sophomore enrolment 77 and the junior class 48, while the senior registration was 45 fewer. The number interning as a requirement for the degree decreased 94. There was an increase in the total enrolment of all classes including the intern year of 14.

STUDENTS LEAVING SCHOOL DURING FIRST TWO YEARS

Of the 5,910 students selected for the freshman class of 1936-1937, 685 failed or withdrew during the first year and 278 more had dropped out by the end of the second medical year. A comparison of these figures with those for 1938-1939 is made in table 23.

While 156 fewer freshmen were enrolled in 1938-1939 than in 1936-1937, there were also 178 fewer students who had discontinued their course by the end of the second year. A decrease in the size of the entering class has not meant a corresponding reduction of the number of students in the clinical years. Further, the failure of 13 per cent of the students to continue beyond the second year suggests that many of those who were admitted lacked the ability to meet the exacting requirements of the medical curriculum.

FEES

The eighty-seven medical schools of the United States and Canada, including those offering courses in the basic medical sciences, have been grouped according to the tuition fees charged for the session 1940-1941 in table 24. An average was computed of the resident fees for each school. Three schools had fees under \$99. These were the Universities of North Dakota, Oklahoma and Texas. Twenty-two schools had fees of \$500 or more, namely the College of Medical Evangelists, Yale, George Washington, Georgetown, Loyola, Tulane, Johns Hopkins, Maryland, Tufts, St. Louis, Washington, Columbia, Cornell, Long Island, New York Medical, New York University, Syracuse, Buffalo, Cincinnati, Hahnemann, Pennsylvania and Pittsburgh. Thirty-three schools in the United States and five in Canada made an additional charge for nonresidents, ranging from \$50 each year by the Universities of Mississippi, Nebraska, Cincinnati and Virginia to \$400 exacted by Louisiana State University School of Medicine. Medical school fees have been increased, as can be noted by a comparison with earlier figures. In 1940 there were two schools in the first group, seven in the second, twenty-three in the third, fourteen in the fourth, twenty-five in the fifth and sixteen in the sixth group.

The lowest additional fee for nonresidents in the United States was \$50, and in Canada one school has a nonresident fee of \$5 for the first and \$10 for the second, third and fourth year. Fifteen schools have a nonresident fee of \$100 or less, eleven have fees between \$101 and \$200, nine from \$201 to \$300 and two from \$301 to \$400, while one school has a reciprocal fee for nonresidents.

TABLE 23.—Students Leaving School During First Two Years

	Class Entering 1936	Class Entering 1939
Freshman enrolment	5,910	5,754
Junior enrolment	4,947	4,929
Loss during first two years	963 —785	785
178 fewer students lost during first two years by the class entering in 1939

Based on fees charged resident students.

The average resident fee charged in medical schools in the United States for the last session was \$386, whereas in 1940 it was \$378, in 1939 \$353 and in 1938 \$342.

CITIZENS OF THE UNITED STATES IN FACULTIES OF MEDICINE ABROAD

Beginning in 1931, citizens of the United States began to migrate to Europe to pursue medical courses. At one time reports indicated that there were approxi-

mately 1,500 such students. By 1939 there were at least 500, studying principally in the extramural schools of Scotland. Completion of the professional education of these students was interrupted by cancellation of passports to combat areas. Some students in the upper classes were permitted to return to complete their training and others went to Switzerland, where at that time visas were still obtainable. It is now impossible for students from this country to secure a medical education in any European country. This problem was considered by the Council on Medical Education and Hospitals at a meeting held in December 1939, and it was of the opinion that the granting of advanced standing on the basis of foreign credentials should be left to the discretion of each medical school. The records indicate that relatively few students have been accepted on this basis by the approved medical schools in this country.

The Council on Medical Education and Hospitals does not grade or classify medical schools outside the United States and Canada. No opportunity is afforded for visiting and inspecting such schools, nor are official reports received from them. The Council therefore has no evidence on which to base a rating. A list of foreign schools which has been published from time to time merely serves as a key to the American Medical Directory and indicates the names of the institutions which physicians now licensed to practice in the United States attended or from which they graduated. In the next edition, because of the inability to verify claims of foreign degrees, it is planned to indicate by the symbol ° that the information given is that furnished by the licensing board and that independent verification by the American Medical Association is lacking. It may be assumed that foreign degrees without this symbol have been officially verified.

DESCRIPTION OF MEDICAL SCHOOLS

ARKANSAS

Little Rock

UNIVERSITY OF ARKANSAS SCHOOL OF MEDICINE, 1209 McAlmont Street.—Organized in 1879 as the Medical Department of Arkansas Industrial University. Present title in 1899. In 1911 the College of Physicians and Surgeons united with it and it became an integral part of the University of Arkansas. The first class was graduated in 1880. Clinical teaching was suspended in 1918 but resumed in 1923. Coeducational since organization. The faculty consists of 29 professors and 128 lecturers and instructors, a total of 157. The curriculum covers four years of nine months each. Entrance requirements are two years of collegiate work. The B.S. Degree in Medicine is conferred at the end of the second year. The fees for the four years for residents of Arkansas are \$280 per year; nonresidents are charged \$225 additional each year. The registration for 1940-1941 was 286, graduates 70. The next session begins Oct. 1, 1941, and ends June 9, 1942. The Dean is Byron L. Robinson, M.D.

CALIFORNIA

Berkeley-San Francisco

UNIVERSITY OF CALIFORNIA MEDICAL SCHOOL, University Campus, Berkeley, Medical Center, San Francisco.—Organized in 1864 as the Toland Medical College. The first class graduated in 1864. In 1873 it became the Medical Department of the University of California. In 1909, by legislative enactment, the College of Medicine of the University of Southern California, at Los Angeles, became a clinical department but was changed to a graduate school in 1914. In 1915 the Hahnemann Medical College of the Pacific was merged, and elective chairs in homeopathic materia medica, and therapeutics were provided. Coeducational since organization. Three years of collegiate work are required for admission. The work of the first year is given at Berkeley and that of the last three years at San Francisco. The faculty is composed of 162 professors and 306 associates and assistants, a total of 468. The course covers four years of eight months each, and an additional fifth year consisting of an internship in a hospital or of special work in a department of the medical school. Fees for the four years, respectively, for residents of California are \$330, \$301, \$296 and \$296, nonresidents are charged \$300 additional each year. The registration for 1940-1941 was 239; graduates, 52. The next session begins Aug. 25, 1941, and ends May 23, 1942. The Acting Dean is President Robert G. Sproul, LL.D., Berkeley.

Loma Linda-Los Angeles

COLLEGE OF MEDICAL EVANGELISTS, Loma Linda, Boyle and Michigan Avenues, Los Angeles.—Organized in 1909. The first class graduated in 1914. The laboratory departments are at Loma Linda, the clinical departments at Los Angeles. Coeducational since organization. The faculty is composed of 47 professors and 325 associates, assistants and instructors, a total of 372. The course covers a period of four years of nine months each and an additional year consisting of an internship in an approved hospital. Three years of collegiate work are required for admission. The total fees are respectively, \$612, \$601, \$612 and \$612. The registration for 1940-1941 was 298, graduates, 91. The next session begins Sept. 1, 1941, and ends May 31, 1942. Because of the existing emergency a special session for one-fourth of the senior class has been arranged and began June 1 and ends Feb. 28. The President is Percy T. Maginn, M.D., Los Angeles. The Dean is E. H. Risley, M.D., Loma Linda; the Associate Dean is W. E. Macpherson, M.D., Los Angeles.

Los Angeles

UNIVERSITY OF SOUTHERN CALIFORNIA SCHOOL OF MEDICINE, 3551 University Avenue.—Organized in 1885 as the University of Southern California College of Medicine. First class graduated in 1888. In 1908,

it became the Los Angeles Medical Department of the University of California. In 1909 the College of Physicians and Surgeons, established in 1904, became the Medical Department of the University of Southern California. Its activities were suspended in 1920, reorganized in May 1928, under present title. The faculty consists of 155 professors and 198 instructors, assistants and others, a total of 353. An internship is required for graduation. Three years of collegiate work are required for admission. Coeducational since organization. Annual fees amount to \$452. The registration for 1940-1941 was 201, graduates, 49. The next session begins Sept. 22, 1941, and ends June 6, 1942. The Dean is Paul S. McKibben, Ph.D.

Stanford University-San Francisco

STANFORD UNIVERSITY SCHOOL OF MEDICINE, University Campus, Stanford University, 2398 Sacramento Street, San Francisco. The main buildings are in San Francisco. The laboratories of anatomy, bacteriology and experimental pathology, chemistry, and physiology are located on the campus at Stanford University, which is thirty miles southeast of San Francisco adjoining the City of Palo Alto. The post office is Stanford University. Organized in 1908, when by agreement the interests of Cooper Medical College were taken over. The first class graduated in 1913. Coeducational since organization. The faculty consists of 132 professors and 144 lecturers, assistants and others, a total of 276. Three years of collegiate work are required for admission. Beginning with session 1941-1942 the four quarter plan, it is expected, will be placed in operation for all classes, admitting one class each year. An internship is a requirement for graduation. The fees for the four years, respectively, are \$530, \$458, \$409 and \$409. The registration for 1940-1941 was 240, graduates, 61. During 1941-1942 the quarters begin September 23, January 5, March 31 and June 18 and ends December 16, March 20, June 10 and August 29. The Dean is Loren Roscoe Chandler, M.D.

COLORADO

Denver

UNIVERSITY OF COLORADO SCHOOL OF MEDICINE, 4200 East Ninth Avenue.—Organized in 1883. Classes were graduated in 1885 and in all subsequent years except 1898 and 1899. Denver and Gross College of Medicine was merged, Jan. 1, 1911. Coeducational since organization. The faculty is composed of 57 professors and 130 lecturers, instructors and assistants, a total of 187. The course covers four years of nine months each. The entrance requirements are three years of collegiate work. The fees for residents of Colorado are, respectively, \$301, \$296, \$281 and \$281. Nonresidents are charged \$245 additional each year. The registration for 1940-1941 was 204, graduates, 45. The next session begins Sept. 24, 1941, and ends June 8, 1942. Advanced students admitted January 5 and March 23, 1942. The Dean is Maurice H. Rees, M.D.

CONNECTICUT

New Haven

YALE UNIVERSITY SCHOOL OF MEDICINE, 333 Cedar Street.—Chartered in 1810 as the Medical Institution of Yale College. Organized in 1812, instruction began in 1813; first class graduated in 1814. A new charter in 1879 changed the name to the Medical Department of Yale College. In 1884, the Connecticut Medical Society surrendered such authority as had been granted by the first charter. In 1887, Yale College became Yale University. Coeducational since 1916. The faculty consists of 176 professors and 233 lecturers and assistants, a total of 407. The requirements for admission are three years of collegiate work. The

course covers four years of nine months each. The fees are, respectively, \$505, \$500, \$500, and \$520. The registration for 1940-1941 was 206, graduates, 51. The next session begins Sept. 22, 1941, and ends June 10, 1942. The Dean is Francis G. Blake, M.D.

DISTRICT OF COLUMBIA

Washington

GEORGETOWN UNIVERSITY SCHOOL OF MEDICINE, 3900 Reservoir Road, N.W.—Organized in 1851. First class graduated in 1852. The faculty is composed of 63 professors, 45 associate professors, 12 assistant professors, 5 adjunct professors, and 152 instructors, a total of 277. A baccalaureate degree is required for admission. The course of study covers four terms of eight and one-half months each. The present fees for each of the four sessions are \$500. The registration for 1940-1941 was 306; graduates, 73. The next session begins Sept. 18, 1941, and ends June 8, 1942. The Dean is David V. McCauley, S.J., Ph.D.

GEORGE WASHINGTON UNIVERSITY SCHOOL OF MEDICINE, 1335 H Street, N.W.—Organized in 1825 as the Medical Department of Columbian College. Also authorized to use the name National Medical College. Classes were graduated in 1826 and in all subsequent years except in 1834 to 1838, and 1861 to 1863, inclusive. The original title was changed to Medical Department of Columbian University in 1873. In 1903 it absorbed the National University Medical Department. In 1904, by an Act of Congress, the title of George Washington University was granted to the institution. Coeducational since 1884. The faculty is composed of 74 professors and 137 instructors, demonstrators and assistants, a total of 211. Two years of collegiate work are required for admission. Beginning with the session 1941-1942 the premedical requirement will be raised to three years. The course covers four years of thirty-six weeks each. The fees for each of the four years are \$550. The registration for 1940-1941 was 260; graduates, 59. The next session begins Sept. 22, 1941, and ends June 10, 1942. Because of the existing emergency a special session (optional) of the senior class has been arranged and began June 9 and ends February 22. The Dean is Walter A. Bloedorn, M.D.

HOWARD UNIVERSITY COLLEGE OF MEDICINE, Fifth and W Streets, N.W.—Chartered in 1867. Organized in 1869. The first class graduated in 1871. Coeducational since organization. Negro students compose a majority of those in attendance. The faculty comprises 34 professors and 75 instructors and assistants, a total of 109. The admission requirements are at least two years of collegiate work. The course covers four years of thirty-three weeks each. The fees are, respectively, \$269, \$269, \$259 and \$266. Registration for 1940-1941 was 151; graduates, 22. The next session begins Sept. 20, 1941, and ends June 5, 1942. The Dean is John Wesley Lawlah, M.D.

GEORGIA

Atlanta

EMORY UNIVERSITY SCHOOL OF MEDICINE, 50 Armstrong Street.—Organized in 1854 as the Atlanta Medical College. Classes graduated 1855 to 1861, when it suspended. Reorganized in 1865. A class graduated in 1865 and each subsequent year except 1874. In 1898 it merged with the Southern Medical College (organized in 1878), taking the name of Atlanta College of Physicians and Surgeons. In 1913 it merged with the Atlanta School of Medicine (organized in 1905), reassuming the name of Atlanta Medical College. Became the Medical Department of Emory University in 1915; assumed present title in 1917. Three years of collegiate work are required for admission. The faculty consists of 14 professors and 176 associates and assistants, a total of 190. The course of study is four years of thirty-two weeks each. The fees for each of the four years are \$338. The registration for 1940-1941 was 218, graduates, 54. The next session begins Sept. 25, 1941, and ends June 8, 1942. The Dean is Russell H. Oppenheimer, M.D.

Augusta

UNIVERSITY OF GEORGIA SCHOOL OF MEDICINE, University Place. Organized in 1828 as the Medical Academy of Georgia, the name being changed to the Medical College of Georgia in 1829. After 1873 it was known as the Medical Department of the University of Georgia. On July 1, 1933 the name was changed to the University of Georgia School of Medicine. Property transferred to the University in 1911. Classes were graduated in 1833 and all subsequent years except 1862 and 1863. Coeducation was begun in 1920. The faculty includes 59 professors and 35 assistants, a total of 94. Three years of collegiate work are required for admission. The course is four years of thirty-four weeks each. The fees for each of the four years are \$225 for residents of Georgia, and \$445 each year for nonresidents. The registration for 1940-1941 was 179, graduates 37. The next session begins Oct. 1, 1941, and ends June 15, 1942. The Dean is G. Lombard Kelly, M.D.

ILLINOIS

Chicago

LOYOLA UNIVERSITY SCHOOL OF MEDICINE, 706 South Wolcott Avenue.—Organized in 1913 by acquisition of Bennett Medical College which had been organized in 1869. Facilities enlarged upon by acquisition of Chicago College of Medicine and Surgery, faculties in basic medical sciences put on full time basis and present title assumed in 1917. Operated as an organic part of Loyola University. Co-educational since organization. Ninety semester hours is the minimum requirement for admission. The course of study is five years, including an internship. The faculty is composed of 32 full time professors and 201 other associate and assistant professors, associates, instructors and assistants, a total of 233. The fees

for each year are \$510, \$515, \$492 and \$521, respectively. The enrollment for 1940-1941 was 270; graduates, 107. Next session for juniors and seniors begins Sept. 8, 1941, for freshmen and sophomores, Sept. 15, 1941, and ends June 6, 1942. The Dean is Francis J. Braceland, M.D.

NORTHWESTERN UNIVERSITY MEDICAL SCHOOL, 303 East Chicago Avenue.—Organized in 1859 as the Medical Department of Lind University. First class graduated in 1860. In 1864 it became independent as the Chicago Medical College. It united with Northwestern University in 1869 but retained the name of Chicago Medical College until 1891, when the present title was taken. Became an integral part of Northwestern University in 1905. Coeducational since 1926. The faculty comprises 29 professors, 126 associate and assistant professors and 361 associates, instructors and clinical assistants, a total of 516. The requirement for admission is three years of collegiate work. The B.S. degree in medicine may be conferred before the end of the senior year. The school operates on the four quarter plan. A hospital internship is required for graduation. The total fees are \$414 each year. The registration for 1940-1941 was 556; graduates, 134. During the academic year 1941-1942 the quarters begin October 1, January 5, March 30 and June 17, and end December 20, March 26, June 6 and August 29. The Dean is J. Roscoe Miller, M.D.

UNIVERSITY OF CHICAGO, THE SCHOOL OF MEDICINE, Fifty-Eighth Street and Ellis Avenue.—Organized in 1924, as a part of the Oslen Graduate School of Science of the University of Chicago. In 1937, when the University of Chicago reorganized its departments, the medical departments were included in the Biological Sciences Division. The work of the first two years in the medical courses has been given to the University Quadrangles since 1899; but the last two years were offered only at Rush Medical College which was affiliated with the university until 1927 when actual work in the clinical departments on the campus began. After that time, candidates for the degree of Doctor of Medicine could take the work of the first two years on the campus and the work of the third and fourth years either on the campus or at the Rush Medical College. Undergraduate courses in the clinical years at Rush Medical College will terminate in June 1942, when the students now enrolled will complete their studies. Thereafter all undergraduate instruction will be given only on the campus of the University. Rush Medical College will be affiliated with the University of Illinois College of Medicine. The faculty of the School of Medicine is composed of 105 professors, 173 associates, instructors and others, a total of 278. The requirements for admission are three years of collegiate work. The B.S. degree in medicine may be obtained during the second year. The curriculum covers twelve quarters of work. Freshmen are admitted in the fall quarter and advanced students in the spring and summer quarters. Sixty-five students are admitted to the first year class in each calendar year. The tuition fee for each of the four years is \$450. The registration for 1940-1941 was 258; graduates 42. During the academic year 1941-1942 the quarters begin June 24, October 7, January 5 and March 30, and end August 28, December 19, March 20 and June 17. All correspondence relating to general policies should be addressed to W. H. Taliaferro, Ph.D., Dean of the Division of Biological Sciences, or to A. C. Bachmeyer, M.D., Associate Dean, and that pertaining to student affairs to Victor Johnson, M.D., Dean of Medical Students.

RUSH MEDICAL COLLEGE, 1758 West Harrison Street.—Chartered in 1837 and taught first class in 1843. First class graduated in 1844. In 1887 the College became the medical department of Lake Forest University, retaining, however, its self-government. This relationship was dissolved in April 1898, and in the same month affiliation with the University of Chicago was established. After 1899 the first two years of the medical course were given on the university campus. Clinical years only were offered at Rush Medical College. In May 1924, under a new agreement, the University of Chicago took over the work of Rush Medical College as a department of the university. The faculty is composed of 138 professors, 163 associates, instructors and others, a total of 301. The tuition fee is \$450 yearly. The registration for 1940-1941 was 212; graduates, 94. The last session begins Sept. 29, 1941, and ends June 9, 1942. The school is in session all year except the month of September. By resolution of the board of trustees of the University of Chicago, undergraduate courses in the clinical years will terminate in June 1942, when the students now enrolled in these courses will have completed their studies. During 1940-1941 arrangements were entered into by the Trustees of Rush Medical College, the Trustees of the University of Chicago, the Trustees of the University of Illinois and the Board of Managers of the Presbyterian Hospital, whereby the University of Chicago returned to the Trustees of Rush Medical College the property and funds belonging to the College. An affiliation was effected between the Presbyterian Hospital and the University of Illinois. This affiliation provides for the teaching of undergraduate students of the University of Illinois in the wards of the Presbyterian Hospital and in the Central Free Dispensary, which now comes under the direction of the Board of Managers of the Presbyterian Hospital. The staff of the Presbyterian Hospital becomes members of the faculty of the medical school of the University of Illinois. A newly constituted Board of Trustees of Rush Medical College will continue to conserve the funds and property of Rush Medical College. This Rush Board retains the Rush charter and endowment of the Rush buildings and equipment and library and certain funds and the power to appoint a faculty as needed. The Rush buildings and equipment and library will be leased to the Presbyterian Hospital for a nominal sum. Under the proposed plan, Rush is at liberty to use its name with any postgraduate or graduate subject of research for which funds may be provided. The Acting Dean of Rush Medical College is Earle Gray, M.D.

UNIVERSITY OF ILLINOIS COLLEGE OF MEDICINE 1853 West Polk Street—Organized in 1882 as the College of Physicians and Surgeons. The first class graduated in 1883. It became the Medical Department of the University of Illinois by affiliation in 1897. Relationship with the university was cancelled in June 1912, and was restored in March 1913, when the present title was assumed. Coeducational since 1898. Three years of collegiate work are required for admission. The curriculum covers four years of thirty-two weeks each and a year of internship in an approved hospital. Senior students enrolled during 1940-1941 were not required to comply with the intern requisite because of the national emergency. The B.S. degree in medicine is conferred at the end of the second year. The faculty is composed of 165 professors and 394 associates, instructors and assistants, a total of 559. The total fees for residents of Illinois are \$260 a year for students of the first and second years, \$310 for the third and fourth, similarly \$410 and \$460 a year for nonresident students. The registration for 1940-1941 was 616 graduates, 302. The next session begins Sept. 29, 1941, and ends June 12, 1942. The Dean is David J. Davis, M.D.

INDIANA

Bloomington-Indianapolis

INDIANA UNIVERSITY SCHOOL OF MEDICINE, Bloomington, 1040 West Michigan Street, Indianapolis—Organized in 1903 but did not give all the work of the first two years of the medical course until 1905. In 1907, by union with the State College of Physicians and Surgeons, the complete course in medicine was offered. In 1908 the Indiana Medical College which was formed in 1905 by the merger of the Medical College of Indiana (organized in 1878), the Central College of Physicians and Surgeons (organized in 1879), and the Fort Wayne College of Medicine (organized in 1879) merged into it. The first class was graduated in 1908. Coeducational since organization. The faculty consists of 270 professors, lecturers, associates and assistants. Three years of collegiate work are required for admission. The B.S. degree in medicine is conferred. The work of the first year is given at Bloomington and the work of the next three years at Indianapolis. The regular fee for the medical course for all four years is \$217 a year for residents of Indiana, and \$422 for nonresidents. The registration for 1940-1941 was 458, graduates, 98. The next session begins Sept. 15, 1941, and ends June 1, 1942. The Dean is Willis D. Gatch, M.D., Indianapolis.

IOWA

Iowa City

STATE UNIVERSITY OF IOWA COLLEGE OF MEDICINE, University Campus—Organized in 1869. First session began in 1870. First class graduated in 1871. Absorbed Drake University College of Medicine in 1913. Coeducational since 1870. The faculty is made up of 56 professors, 74 lecturers, demonstrators and assistants, a total of 130. Three years of collegiate work are required for admission. The B.A. degree in the combined course of liberal arts and medicine is conferred. The course of study covers four years of thirty-four weeks each. The tuition fee is \$226 each year for residents of Iowa and \$490 for nonresidents. The registration for 1940-1941 was 286, graduates, 80. The next session begins Sept. 25, 1941, and ends June 1, 1942. The Dean is Eben Murchison MacEwen, M.D.

KANSAS

Lawrence-Kansas City

UNIVERSITY OF KANSAS SCHOOL OF MEDICINE, Lawrence, 39th Street and Rainbow Boulevard, Kansas City—Organized in 1880. It offered only the first two years of the medical course until 1905, when it merged with the Kansas City (Mo.) Medical College, founded in 1869, the College of Physicians and Surgeons founded in 1894, and the Medico-Chirurgical College, founded in 1897. Absorbed Kansas Medical College in 1913. The first class graduated in 1906. The clinical courses are given at Kansas City. Coeducational since 1880. The faculty includes 74 professors and 147 instructors, assistants and others, a total of 221. The requirement for admission is three years of collegiate work. The B.S. degree in medicine is conferred at the end of the second year. The course covers four years of nine months each. The total fees for residents of the state are, respectively, \$159, \$170, \$165 and \$167. For nonresidents the fees are, respectively, \$269, \$345, \$415 and \$417. The registration for 1940-1941 was 289, graduates, 71. The next session begins Sept. 17, 1941, and ends June 8, 1942. The Dean is H. R. Wahl, M.D., Kansas City.

KENTUCKY

Louisville

UNIVERSITY OF LOUISVILLE SCHOOL OF MEDICINE, 101 West Chestnut Street—Organized in 1837 as Louisville Medical Institute. The first class graduated in 1838 and a class graduated each subsequent year except 1863. In 1846 the name was changed to University of Louisville Medical Department. In 1907 it absorbed the Kentucky University Medical Department, in 1908, the Louisville Medical College, the Hospital College of Medicine and the Kentucky School of Medicine. In 1922 it changed its name to the University of Louisville School of Medicine. Coeducational since organization. Two years of collegiate work are the minimum requirement for admission. Preference is given applicants with a degree or three college years leading to a degree. The faculty numbers 77 professors and 115 assistants, instructors and others, a total of 192. Course covers four years of thirty-two weeks each, exclusive of vacations and examinations. Fees are, respectively, \$450, \$450, \$450 and \$460. The registration for 1940-1941 was 345, graduates, 89. The next session begins Sept. 15, 1941, and ends June 2, 1942. The Dean is John Walker Moore, M.D.

LOUISIANA

New Orleans

LOUISIANA STATE UNIVERSITY SCHOOL OF MEDICINE, 1542 Tulane Avenue—Organized January 1931 as Louisiana State University Medical Center. Present title in 1939. Coeducational. First session October 1931, with students of first and third year. Faculty comprises 28 professors and 156 assistant professors, instructors and assistants, a total of 184. Course covers four years of no less than 32 weeks each. A minimum of three years' collegiate work is required for admission. Total fees, \$134 each year for residents of Louisiana, additional tuition of \$400 each year for nonresidents. The registration for 1940-1941 was 338, graduates, 73. The next session begins Sept. 8, 1941, and ends May 30, 1942. Because of the existing emergency a special session of the senior class has been arranged and began June 16 and ends February 14. The Dean is B. I. Burns, M.D.

TULANE UNIVERSITY OF LOUISIANA SCHOOL OF MEDICINE, 1430 Tulane Avenue—Organized in 1834 as the Medical College of Louisiana. Classes were graduated in 1835 and in all subsequent years except 1863, 1865, inclusive. It became the Medical Department of the University of Louisiana in 1847, and in turn, the Medical Department of the Tulane University of Louisiana in 1884. Present title in 1913. Coeducational since 1915. The faculty comprises 30 professors and 222 associate and assistant professors, instructors and assistants, a total of 252. The course covers four years of thirty-two weeks each. A minimum of three years of collegiate work is required for admission. Total fees are, respectively, \$552, \$552, \$537 and \$547. The registration for 1940-1941 was 483, graduates, 121. The next session begins Sept. 25, 1941, and ends June 10, 1942. Because of the existing emergency, a special session (optional) of the senior class has been arranged and began June 16, students will be permitted to finish two months earlier but will graduate with the regular class. The Dean is Maxwell E. Latham, M.D.

MARYLAND

Baltimore

JOHNS HOPKINS UNIVERSITY SCHOOL OF MEDICINE, 710 North Washington Street—The nucleus of a Medical Faculty was constituted in 1883. Systematic postgraduate instruction in pathology and bacteriology was begun in 1886. School was fully organized and opened in 1893. The first class graduated in 1897. Coeducational since organization. The faculty consists of 71 professors and 417 instructors, assistants and others, a total of 488. The requirement for admission is a collegiate degree. The course extends over four years of eight and one-half months each. The total fees are, respectively, \$624, \$623, \$623 and \$623. The registration for 1940-1941 was 282, graduates, 72. The next session begins Sept. 23, 1941, and ends June 2, 1942. The Dean is Alvin M. Chesney, M.D.

UNIVERSITY OF MARYLAND SCHOOL OF MEDICINE AND COLLEGE OF PHYSICIANS AND SURGEONS, Lombard and Greene Streets—Organized in 1807 as the College of Medicine of Maryland. The first class graduated in 1810. In 1812 it became the University of Maryland School of Medicine. Baltimore Medical College was merged with it in 1913. In 1915 the College of Physicians and Surgeons of Baltimore was merged and the present name assumed. Coeducational since 1918. The faculty consists of 45 professors and 267 associate and assistant professors and others, a total of 312. Three years of collegiate work are required for admission. The course covers four years of eight months each. The fees are, respectively, \$505, \$495, \$495, \$510 for residents of the state, for nonresidents the fees are \$150 additional each year. The registration for 1940-1941 was 369, graduates, 92. The next session begins Sept. 25, 1941 and ends June 6, 1942. The Acting Dean is H. Boyd Wylie, M.D.

MASSACHUSETTS

Boston

BOSTON UNIVERSITY SCHOOL OF MEDICINE, 80 East Concord Street—Organized in 1873 as a homeopathic institution. In 1874 the New England Female Medical College, founded in 1848, was merged into it. The first class was graduated in 1874. Became nonsectarian in 1918. Coeducational since organization. Three years of collegiate work are required for admission. The faculty includes 24 professors, 175 associates and others, a total of 199. The course covers four years. Total fees for each of the four years respectively, are \$479, \$475, \$475, \$490. The registration for 1940-1941 was 193, graduates, 33. The next session begins Sept. 18, 1941, for 1st, 2d and 3d year students, and Sept. 8, 1941, for 4th year students, and ends June 8, 1942. Because of the existing emergency a special session (optional) of the senior class has been arranged and began June 8 and ends March 1. The Dean is Bennett F. Avery, M.D.

HARVARD MEDICAL SCHOOL, 25 Shattuck Street—Organized in 1782. The first class graduated in 1788. It has a faculty of 168 professors and 470 other instructors and assistants, a total of 638. Two years of collegiate work are required for admission. The total fees for each of the four years are \$420, plus \$5 the first year for matriculation. The registration for 1940-1941 was 528, graduates 137. The next session begins Sept. 22, 1941, and ends June 18, 1942. Because of the existing emergency a special session (optional) of the senior class has been arranged and began June 1 and ends March 1. The Dean is C. Sidney Burwell, M.D.

TUFTS COLLEGE MEDICAL SCHOOL, 416 Huntington Avenue—Organized in 1893 as the Medical Department of Tufts College. The first class graduated in 1894. Coeducational since 1894. It has a faculty of 91 professors and 284 assistant lecturers and others, a total of 375. A bachelor's degree is required for admission. The course covers four years of eight months each. The total fees for each of the four years

are \$512, \$507, \$507 and \$517. The registration for 1940-1941 was 386, graduates, 90. The next session begins Sept 24, 1941 and ends June 14, 1942. Because of the existing emergency, a special session (optional) of the senior class has been arranged and began June 1. Students will complete their work earlier but will graduate with the regular class in June. The Dean is A. Warren Stearns, M.D.

MICHIGAN

Ann Arbor

UNIVERSITY OF MICHIGAN MEDICAL SCHOOL—Organized in 1850 as the University of Michigan Department of Medicine and Surgery. The first class graduated in 1851. Present title assumed in 1915. Coeducational since 1870. It has a faculty of 25 professors, 21 associate professors, 25 assistant professors, 126 assistants, instructors and lecturers, a total of 197. The entrance requirements are ninety semester hours. The curriculum covers four years of nine months each. The total fees for Michigan students are \$250 for each of the four years respectively, for nonresidents \$400 a year. The registration for 1940-1941 was 460, graduates, 117. The next session begins Sept 29, 1941, and ends June 20, 1942. The Dean is A. C. Furstenberg, M.D.

Detroit

WAYNE UNIVERSITY COLLEGE OF MEDICINE, 1516 St. Antoine Street. Organized as the Detroit College of Medicine in 1885 by consolidation of Detroit Medical College, organized in 1868, and the Michigan College of Medicine organized in 1880. Reorganized with the title of Detroit College of Medicine and Surgery in 1913. The first class graduated in 1886. In 1918 it became a municipal institution under the control of the Detroit Board of Education. In 1934 the name was changed by action of the Detroit Board of Education to Wayne University College of Medicine as a part of the program of consolidation of the Detroit City Colleges into a university system. Coeducational since 1917. Entrance requirement is an academic degree or 90 semester hours of academic credit with "combined degree" guaranteed by school of arts and sciences. The faculty consists of 45 professors, 262 lecturers and others, a total of 307. The course covers four years of nine months each and a fifth year of intern work. The total fees for each of the first four years are, for Wayne County residents \$325 and for nonresidents outside of Wayne County \$425. The registration for 1940-1941 was 248, graduates 58. The next session begins September 15, 1941, and ends June 20, 1942. Because of the existing emergency a special session (optional) of the senior class has been arranged and began June 30 and ends February 28. The Dean is Edgar H. Norris, M.D.

MINNESOTA

Minneapolis

UNIVERSITY OF MINNESOTA MEDICAL SCHOOL—Organized in 1883 as the University of Minnesota College of Medicine and Surgery, reorganized in 1888 by absorption of St. Paul Medical College and Minnesota Hospital College. The first class graduated in 1889. In 1908 the Minneapolis College of Physicians and Surgeons organized in 1883 was merged. Present title in 1913. Coeducational since organization. The faculty includes 204 professors of whom 77 are on full time appointment and 127 on part time and 134 instructors, 29 of whom are on full-time appointment and 105 on part time, a total of 338. The curriculum covers four years of nine months each, and a year's internship in an approved hospital. The school is operated on the four-quarter plan. The entrance requirements are three years of university work which must include six semester credits of rhetoric, eight semester credits of physics, thirteen credits of general chemistry qualitative and quantitative analysis, organic and physical chemistry, eight credits of general zoology and genetics and eugenics, four credits of general psychology, and a reading knowledge of scientific German, with a 'C' average in all subjects and in the sciences. Students are required to meet the requirements for a degree of B.S. or B.A. before receiving the degree of Bachelor of Medicine (M.B.), which is granted at the end of the four-year course. The M.D. degree is conferred after a year of intern work, or of advanced laboratory work, or of public health work has been completed. Students are graduated at the end of any quarter in which work is completed and examinations passed. Total fees are \$256 for residents and \$412 for nonresidents each year of three quarters. The registration for 1940-1941 was 431, graduates 132. During the academic year 1940-1941 the quarters begin September 29, January 5, March 30 and June 17, and end December 18, March 18, June 12 and August 28. The Dean is Harold S. Diehl, M.D.

MISSOURI

St. Louis

ST. LOUIS UNIVERSITY SCHOOL OF MEDICINE, 1402 South Grand Boulevard. Organized in 1901 as the Marion Sims Beaumont Medical College by union of Marion Sims Medical College, organized in 1890, and Beaumont Hospital Medical College, organized in 1886. First class graduated in 1902. It became the Medical School of St. Louis University in 1903. The faculty is composed of 77 professors and 231 instructors and assistants, a total of 308. The completion of three years of college study is the minimum admission requirement but students presenting more than six credits in excess of the minimum are accepted by preference. The curriculum covers four years of thirty-two weeks each. The summer is optional and offers courses academically equivalent to those in the regular

session. The total fees are, respectively, \$530, \$525, \$525 and \$565. The registration for 1940-1941 was 421, graduates, 99. The next session begins Sept 23, 1941, and ends June 1, 1942. The Dean is Alphonse M. Schwitala, S.J., Ph.D.

WASHINGTON UNIVERSITY SCHOOL OF MEDICINE, Kingshighway and Euclid Avenue—Organized in 1842 as the Medical Department of St. Louis University. The first class graduated in 1843. In 1855 it was chartered as an independent institution under the name of St. Louis Medical College. In 1891 it became the Medical Department of Washington University. In 1899 it absorbed the Missouri Medical College. Coeducational since 1918. The faculty comprises 131 professors and 260 lecturers, instructors and others, a total of 396. Four years of collegiate work are required for admission. The B.S. degree in medicine is conferred at the end of the third or fourth year. The course is four years of eight months each. The total fees are, respectively, \$523, \$518, \$518 and \$523. The registration for 1940-1941 was 351, graduates, 97. The next session begins Sept 25, 1941, and ends June 9, 1942. The Dean is Philip A. Shaffer, Ph.D.

NEBRASKA

Omaha

CREIGHTON UNIVERSITY SCHOOL OF MEDICINE, 306 North Fourteenth Street—Organized in 1892 as the John A. Creighton Medical College. The first class graduated in 1893. Present title in 1921. Coeducational since organization. It has a faculty of 75 professors and 76 instructors, lecturers and assistants, a total of 151. Three years of collegiate work required for admission. The B.S. degree in medicine is conferred at the end of the second year. The curriculum covers four years of eight months each. The total fees for the four years are, respectively, \$398, \$393, \$348 and \$356, and \$100 additional each year for students who have not taken the major part of their work at Creighton University School of Arts and Sciences. The registration for 1940-1941 was 223, graduates, 64. The next session begins Sept 23, 1941, and ends June 4, 1942. The Dean is Charles M. Wilhelm, M.D.

UNIVERSITY OF NEBRASKA COLLEGE OF MEDICINE, Forty Second Street and Dewey Avenue—Organized in 1881 as the Omaha Medical College. The first class graduated in 1882. It became the Medical Department of Omaha University in 1891. In 1902 it affiliated with the University of Nebraska, with the present title. The instruction of the first two years was given at Lincoln and of the last two at Omaha until 1913, when the work of all four years was transferred to Omaha. Coeducational since 1882. The faculty is composed of 78 professors and 54 lecturers and instructors, a total of 132. Three years of collegiate work are required for admission. The B.S. degree in medicine is conferred at the end of the second year. The fees for the four years, respectively, are \$219, \$214, \$214 and \$214. The registration for 1940-1941 was 317, graduates, 77. The next session begins Sept 22, 1941, and ends June 8, 1942. The Dean is C. W. M. Poynter, M.D.

NEW YORK

Albany

ALBANY MEDICAL COLLEGE, 47 New Scotland Avenue—Organized in 1838. The first class graduated in 1839. It became the Medical Department of Union University in 1873. In 1915 Union University assumed educational control. Coeducational since 1915. The faculty is composed of 86 professors and 109 instructors, assistants and others, a total of 195. A collegiate degree is required for admission, however, students who have completed three years of college work and who have proper specific qualifications will be admitted. This change in the requirements for admission has been instituted for the duration of the present national emergency. The curriculum covers four years of eight months each. The total fees are respectively, \$555, \$530, \$515 and \$525. The registration for 1940-1941 was 140, graduates, 29. The next session begins Sept 8, 1941, and ends June 8, 1942. The Dean is R. S. Cunningham, M.D.

Brooklyn

LONG ISLAND COLLEGE OF MEDICINE, 350 Henry Street—Organized in 1858 as the Long Island College Hospital. The first class graduated in 1860 and the last class in 1930. Reorganized with a new charter in 1930 as the present institution. The first class graduated in 1931. Coeducational. It has a faculty of 119 professors, associate, assistant, clinical and assistant clinical professors, and 183 lecturers, associates, instructors, assistants and others, a total of 302. Ninety semester hours of collegiate work are required for admission. The course covers four years. The total fee for each of the four years is \$610. The registration for 1940-1941 was 365, graduates, 81. The next session begins Sept 15, 1941, for the fourth year and Sept 29, 1941, for the other years and ends June 9, 1942. The Dean is Jean Alonzo Curran, M.D.

Buffalo

UNIVERSITY OF BUFFALO SCHOOL OF MEDICINE, 24 High Street—Organized in 1846. The first class graduated in 1847. It absorbed the Medical Department of Niagara University in 1898. Coeducational since organization. The faculty is composed of 94 professors and 192 associates, assistants and others, a total of 283. The minimum requirement for admission is two years of collegiate work including certain prescribed science courses. The course covers four years of eight months each. The total fees are respectively, \$530, \$525, \$520 and \$530. The registration for 1940-1941 was 266, graduates, 66. The next session begins Oct 1, 1941 and ends June 13, 1942. The Dean is Elward W. Kech, M.D.

New York

COLUMBIA UNIVERSITY COLLEGE OF PHYSICIANS AND SURGEONS, 630 West One Hundred and Sixty Eighth Street—The medical faculty of Columbia College, then known as King's College, was organized in 1767. Instruction was interrupted by the War of the Revolution. The faculty was reestablished in 1792 and merged in 1814 with the College of Physicians and Surgeons, which had received an independent charter in 1807. In 1860 the College of Physicians and Surgeons became the Medical Department of Columbia College. This merger became permanent by legislative enactment in 1891. Columbia College became Columbia University in 1896. The medical school has been coeducational since 1917. The faculty is composed of 280 professors and 592 instructors, demonstrators and others a total of 872. Three years of collegiate work are required for admission. The work covers four years of eight months each. The total fees are, respectively, \$545, \$530, \$530 and \$550. The registration for 1940-1941 was 411, graduates 104. The next session begins Sept. 18, 1941, and ends June 2, 1942. Because of the existing emergency a special session (optional) of the senior class has been arranged and began June 1 and will end in February. The Dean is Willard C. Rappleye, M.D.

NEW YORK MEDICAL COLLEGE FLOWER AND FIFTH AVENUE HOSPITALS, 1 East 105th Street—Organized in 1828. Incorporated in 1860 as the Homeopathic Medical College of the State of New York. The title New York Homeopathic Medical College was assumed in 1869, the title New York Homeopathic Medical College and Hospital in 1887, the title New York Homeopathic Medical College and Flower Hospital in 1908, the title New York Medical College and Flower Hospital in 1936, the present title of New York Medical College Flower and Fifth Avenue Hospitals, June 22, 1938. The first class graduated in 1861. Coeducational since 1919. A baccalaureate degree or its equivalent required for admission. The course covers four years of eight months each. It has a faculty of 64 professors and associate professors, 39 assistant professors, and 250 lecturers and assistants a total of 353. The fees are, respectively, \$645, \$635, \$635 and \$665. The registration for 1940-1941 was 305, graduates, 67. The next session begins Sept. 13, 1941, and ends June 5, 1942. The Acting Dean is J. A. W. Hetrick, M.D.

NEW YORK UNIVERSITY COLLEGE OF MEDICINE, 477 First Avenue—The Medical Department of New York University (then called the University of the City of New York) was organized in 1841. In 1898 it united with the Bellevue Hospital Medical College, organized in 1861, under the name of University and Bellevue Hospital Medical College. In 1935 the name was changed to New York University College of Medicine. Coeducational since 1919. The faculty is composed of 163 professors, associate, assistant clinical and assistant clinical professors, and 377 lecturers, instructors and others, a total of 540. The course covers four years. Entrance requirements are that all candidates must have completed three full years of study in an approved college of arts and sciences. The fees for each of the four years are \$600. The registration for 1940-1941 was 499, graduates 122. The next session begins Sept. 17, 1941, and ends June 10, 1942. The Dean is Carrier McEwen, M.D.

CORNELL UNIVERSITY MEDICAL COLLEGE, 1300 York Avenue—Organized in 1898. Coeducational since organization. The first year was given to approximately one third of the class at Ithaca, but in 1938 this branch was discontinued and all work is now given in New York City. The faculty is composed of 152 professors and 315 assistants, lecturers, instructors and others a total of 467. All candidates for admission must be graduates of approved colleges or scientific schools or seniors of approved colleges that will permit them to substitute the first year of this medical school for the fourth year of their college course and will confer on them the baccalaureate degree on the completion of the first year's work. The fees are, respectively, \$620, \$610, \$615 and \$525. The registration for 1940-1941 was 294, graduates, 63. The next session begins Sept. 16, 1941, and ends June 10, 1942. The Dean is William S. Ladd, M.D.

Rochester

UNIVERSITY OF ROCHESTER SCHOOL OF MEDICINE AND DENTISTRY, 260 Crittenden Boulevard—Organized in 1925 as the Medical Department of the University of Rochester. Coeducational since organization. The faculty is composed of 64 professors, 220 lecturers, assistants, instructors and others, a total of 284. The work embraces a graded course of four years of nine months each. Three years of collegiate work are required for admission. The total fees for each year are \$500. The registration for 1940-1941 was 202, graduates 41. The next session begins Sept. 15, 1941, and ends June 13, 1942. The Dean is George Hoyt Whipple, M.D.

Syracuse

SYRACUSE UNIVERSITY COLLEGE OF MEDICINE, 766 Irving Avenue—Organized in 1872, when the Geneva Medical College chartered in 1834, was removed to Syracuse under the title 'The College of Physicians and Surgeons of Syracuse University'. Present title assumed in 1875, when a compulsory three year graded course was established. The first class graduated in 1873 and a class graduated each subsequent year. In 1889 the amalgamation with the university was made complete. Course extended to four years in 1896. Coeducational since organization. The faculty is composed of 48 professors and 181 associate and assistant professors, lecturers and instructors a total of 229. Three years of a recognized college course are required for admission. The course covers four years of thirty four weeks each. The fee for each of the first three years is \$600, for the fourth year, \$610. The enrollment for 1940-1941 was 164 graduates, 42. The next session begins Sept. 22, 1941, and ends June 8, 1942. The Dean is H. G. Weiskotten, M.D.

NORTH CAROLINA

Durham

DUKE UNIVERSITY SCHOOL OF MEDICINE—Organized in 1925. The first class was admitted, Oct. 1, 1930. Coeducational. The faculty is composed of 10 professors and 178 associate and assistant professors, lecturers, instructors and assistants, a total of 188. The entrance requirements are ninety hours of collegiate work. The academic year consists of four quarters of eleven weeks each. Students either may study four quarters each year after the first year, and if satisfactory will receive the M.D. certificate after three and one quarter calendar years, or three quarters in each year, and if satisfactory will be graduated after four calendar years. The B.S. degree in medicine may be conferred for special work after six quarters. Students are urged to spend three years in hospital or laboratory work after graduation and must give assurance satisfactory to the executive committee that they will spend at least two years. The fees are \$450 for each year of three quarters. The registration for 1940-1941 was 262, graduates, 65. During 1941-1942 the quarters begin October 2, January 5, March 30 and June 23 and end December 20, June 13, March 21 and September 5. The Dean is Wilbur C. Davison, M.D.

OHIO

Cincinnati

UNIVERSITY OF CINCINNATI COLLEGE OF MEDICINE, Eden and Bethesda Avenues—Organized in 1909 by the union of the Medical College of Ohio (founded in 1819) with the Miami Medical College (founded in 1852). The Medical College of Ohio became the Medical Department of the University of Cincinnati in 1896. Under a similar agreement, March 2, 1909, the Miami Medical College also merged with the University when the title of Ohio Miami Medical College of the University of Cincinnati was taken. Present title assumed in 1915. Coeducational since organization. Candidates for admission to the freshman class must present three years of college preparation of not less than ninety hours. Liberal Arts students of the University of Cincinnati may sign up for the seven year combined Liberal Arts and Medical program. The B.Sc. degree is granted on the joint recommendation of the Faculties of the Colleges of Liberal Arts and Medicine at the end of the first medical year. The faculty consists of 112 professors, associate and assistant professors, 350 instructors, etc., a total of 462. The course covers four years of eight months each, on the completion of which the M.D. degree is granted. Beginning with the fall session of 1941-1942 the fees will be as follows: For legal residents of Cincinnati \$485 a year, plus breakage fees, (\$50 additional for those not legal residents of Cincinnati). The registration for 1940-1941 was 306, graduates 151. The next session begins Sept. 22, 1941, and ends June 5, 1942. Because of the existing emergency a special session (optional) of the senior class has been arranged and began June 23. Students will complete the required work in February but will graduate with the regular class in June. The Dean is Stanley Dorst, M.D.

Cleveland

WESTERN RESERVE UNIVERSITY SCHOOL OF MEDICINE, 2109 Adelbert Road—Organized in 1843 as the Cleveland Medical College in cooperation with Western Reserve College. The first class graduated in 1844. It assumed the present title in 1881. In 1910 the Cleveland College of Physicians and Surgeons was merged. Coeducational since 1919. The faculty includes 87 professors and 236 lecturers, assistants and others, a total of 323. The curriculum covers three years of nine months each and one year of ten months. Three years of collegiate work are required for admission and a baccalaureate degree for graduation. The total fees are, respectively, \$553, \$537, \$516 and \$526. The registration for 1940-1941 was 282, graduates 63. The next session begins Sept. 25th, 1941, and ends June 17th, 1942. The Dean is Torald Sollmann, M.D.

Columbus

OHIO STATE UNIVERSITY COLLEGE OF MEDICINE, Neil and Eleventh Avenues—Organized in 1907 as the Starling Ohio Medical College by the union of Starling Medical College (organized in 1847 by charter granted by the State Legislature changing the name from Willoughby Medical College, which was chartered March 3, 1834) with the Ohio Medical University (organized 1890). In 1914 it became an integral part of the Ohio State University with its present title. Coeducational since organization. The faculty consists of 79 professors, associate and assistant professors, 77 lecturers, instructors, demonstrators and others, a total of 156. Three years of collegiate work are required for admission. The course covers four years of thirty four weeks each. Tuition fees are \$327 for the first year, and \$312 for each of the other three years for residents of Ohio and \$150 additional for nonresidents. The registration for 1940-1941 was 295, graduates, 68. The next session begins Sept. 30, 1941, and ends June 15, 1942. The Dean is Hardy A. Kemp, M.D.

OKLAHOMA

Oklahoma City

UNIVERSITY OF OKLAHOMA SCHOOL OF MEDICINE, 801 East Thirteenth Street—Organized in 1900. Until 1910 gave only the first two years of the medical course at Norman, Oklahoma, after which a clinical department was established at Oklahoma City by taking over the Medical School of Epworth University. The first class graduated in 1911. Coeducational since organization. Since September, 1928, the entire four year course has been given in Oklahoma City. It has a faculty of 28 professors, 27 associate professors, 20 assistant professors and 125 associate lecturers, visiting lecturers, instructors and assistants a total of 200. Three years

of college work are required for admission. The course covers four years of nine months each. Fees: \$50 "Maintenance and Incidental Fee" per semester. Other annual course fees average \$128, \$95, \$53, and \$58, in the order given, beginning with the freshman year. For students not residents of Oklahoma there is a tuition charge of \$400 a year, plus laboratory and course fees as indicated for the different years. The registration for 1940-1941 was 235; graduates 54. The next session begins Sept. 15, 1941, and ends June 8, 1942. The Dean is Robert U. Patterson, M.D.

OREGON

Portland

UNIVERSITY OF OREGON MEDICAL SCHOOL, Marquam Hill.—Organized in 1887. The first class graduated in 1888, and a class graduated each subsequent year except 1898. The Willamette University Medical Department was merged in 1913. Coeducational since organization. It has a faculty of 91 professors and 164 lecturers, assistants and others, a total of 255. Entrance requirements are three years of collegiate work. The course covers four years of thirty-three weeks each. The total fees are, respectively, \$380, \$375, \$370 and \$376 for residents of Oregon, and \$60 a year additional for nonresidents. The registration for 1940-1941 was 248; graduates, 62. The next session begins Oct. 2, 1941, and ends June 13, 1942. The Dean is Richard B. Dillehunt, M.D.

PENNSYLVANIA

Philadelphia

THE HAHNEMANN MEDICAL COLLEGE AND HOSPITAL OF PHILADELPHIA, 235 North Fifteenth Street.—Organized in 1848 as The Homeopathic Medical College of Pennsylvania. In 1869 it united with The Hahnemann Medical College of Philadelphia, taking the latter title. Assumed present title in 1885. The first class graduated in 1849. Coeducational beginning with 1941-1942 session. Three years of collegiate work in an approved college of arts and sciences are required for admission. It has a faculty of 80 professors and 158 lecturers, instructors, and others, a total of 238. The work covers four years of eight months each. Fees are, respectively, \$515, \$512, \$512 and \$535. The registration for 1940-1941 was 544; graduates, 130. The next session begins Sept. 22, 1941, and ends June 11, 1942. The Dean is William A. Pearson, M.D.

JEFFERSON MEDICAL COLLEGE OF PHILADELPHIA, 1025 Walnut Street.—Organized in 1825 as the Medical Department of Jefferson College, Canonsburg, Pa. It was chartered with its present title in 1838. Classes have been graduated annually beginning 1826. In 1838 a separate university charter was granted without change of title, since which time it has continued under the direction of its own board of trustees. It has a faculty of 79 professors, associate and assistant professors and 204 associates, lecturers, demonstrators and instructors, a total of 283. Four years of college work and a bachelor's degree are required for admission. The course of study covers four years of eight and one-half months each. The total fees are, respectively, \$455, \$440, \$430 and \$430. The registration for 1940-1941 was 508; graduates, 120. The next session begins Sept. 17, 1941, and ends June 5, 1942. The Acting Dean is Randle C. Rosenberger, M.D.

TEMPLE UNIVERSITY SCHOOL OF MEDICINE, 3400 North Broad Street.—Organized in 1901. The first class graduated in 1904. Coeducational since organization. The faculty numbers 33 professors and 223 associates, assistants and others, a total of 256. Three years of collegiate work are required for admission. The fees for each of the four years, respectively, are \$500, \$490, \$480 and \$500. The registration for 1940-1941 was 435; graduates, 112. The next session begins Sept. 17, 1941, and ends June 11, 1942. The Dean is William N. Parkinson, M.D.

UNIVERSITY OF PENNSYLVANIA SCHOOL OF MEDICINE, Thirty-Sixth and Pine Streets.—Organized in 1765. Classes were graduated in 1768 and in all subsequent years except 1772 and 1775-1779, inclusive. The original title was the Department of Medicine, College of Philadelphia. The present title was adopted in 1909. It granted the first medical diploma issued in America. In 1916 it took over the Medico-Chirurgical College of Philadelphia to develop it as a graduate school. Coeducational since 1914. The faculty consists of 125 professors, associate and assistant professors, and 429 lecturers, associates, instructors and others, a total of 554. Three years of collegiate work are required for admission. The course covers four years of thirty-three weeks each. The tuition fee is \$500 each year, with a deposit fee of \$15, a general fee including student health of \$15 and a matriculation fee of \$5. The registration for 1940-1941 was 486; graduates, 125. The next session begins Sept. 22, 1941, and ends June 10, 1942. Because of the existing emergency, the senior year will begin September 2 and end before May 1. The Dean is William Pepper, M.D.

WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA, Henry Avenue and Abbottsford Road, East Falls.—Organized in 1850. Classes were graduated in 1852 and in all subsequent years except 1862. It has a faculty of 77 professors and 64 assistants, lecturers and others, a total of 141. At least three years of collegiate work are required for admission and candidates with a degree are given preference. The curriculum covers four years of eight and one-half months each. Total fees are \$450 yearly. The registration for 1940-1941 was 115; graduates 23. The next session begins Sept. 17, 1941, and ends June 10, 1942. The Dean is Margaret D. Craighill, M.D.

Pittsburgh

UNIVERSITY OF PITTSBURGH SCHOOL OF MEDICINE, Bigelow Boulevard.—Organized in 1886, as the Western Pennsylvania Medical College and in 1908 became an integral part of the University of Pittsburgh, removing to the university campus in 1910. The first class graduated in 1887. Coeducational since 1899. The faculty is composed of 30 professors and 348 associates, assistants and others, a total of 378. Entrance

requirements are two years of collegiate work. The course of study is four years of eight months each. The total fees are \$500 each year. The registration for 1940-1941 was 291; graduates, 55. The next session begins Sept. 22, 1941, and ends June 10, 1942. The Dean is W. S. McElroy, M.D.

SOUTH CAROLINA

Charleston

MEDICAL COLLEGE OF THE STATE OF SOUTH CAROLINA, 16 Lucas Street.—Organized in 1823 as the Medical College of South Carolina. The first class graduated in 1825. In 1832 a medical college bearing the present title was chartered and the two schools continued as separate institutions until they were merged in 1838. Classes were graduated in all years except 1862 to 1865, inclusive. In 1913, by legislative enactment, it became a state institution. Coeducational from 1895 to 1912, when privileges for women were withdrawn, being restored in 1917. It has a faculty of 49 professors and 42 associates, instructors and others, a total of 91. The course covers four years of eight months each. Three years of collegiate work are required for admission. The total fees are \$272 each year. Fees for nonresidents of the state, \$422 each year. The enrollment for 1940-1941 was 173; graduates, 45. The next session begins Sept. 25, 1941, and ends June 4, 1942. The Dean is Robert Wilson, M.D.

TENNESSEE

Memphis

UNIVERSITY OF TENNESSEE COLLEGE OF MEDICINE, 874 Union Avenue.—Organized in 1876 at Nashville as Nashville Medical College. First class graduated 1877, and a class graduated each subsequent year. Became Medical Department of University of Tennessee in 1879. In 1909 it united with the Medical Department of the University of Nashville to form the joint Medical Department of the Universities of Nashville and Tennessee. This union was dissolved in 1911. The trustees of the University of Nashville by formal action of that board named the University of Tennessee College of Medicine as its legal successor. In 1911 it moved to Memphis, where it united with the College of Physicians and Surgeons. The Memphis Hospital Medical College was merged in 1913. Lincoln Memorial University Medical Department was merged in 1914. Coeducational since 1911. The faculty includes 106 professors and 146 assistants, instructors and others, a total of 252. Two years of collegiate work are required for admission. The B.S. degree in medicine is conferred at the end of the second year. The fees are \$120 quarterly. For residents of the state the charge is reduced \$50 each quarter. The registration for 1940-1941 was 461; graduates, 110. During the academic year of 1941-1942 the quarters begin July 8, Sept. 25, Jan. 2, and March 23, and end Sept. 24, Dec. 13, March 21 and June 10. The Dean is O. W. Hyman, Ph.D.

Nashville

MEHARRY MEDICAL COLLEGE, Eighteenth Avenue North and Heffernan Street. (For Negro Youth).—This school was organized in 1876 as the Meharry Medical Department of Central Tennessee College, which became Walden University in 1900. First class graduated in 1877. Obtained new charter independent of Walden University in 1915. Coeducational since 1876. The faculty is made up of 49 professors and 30 instructors and lecturers, a total of 79. Three years' work in a college of liberal arts is required for admission. The curriculum covers four years of thirty-two weeks each. Tuition fees are, respectively, \$300, \$290, \$280 and \$295 each year. The registration for 1940-1941 was 216; graduates, 48. The next session begins Oct. 1, 1941, and ends May 26, 1942. The Dean is Edward L. Turner, M.D.

VANDERBILT UNIVERSITY SCHOOL OF MEDICINE, Twenty-First Street at Edgemoor.—This school was founded in 1874. The first class graduated in 1875. Coeducational since September 1925. The faculty numbers 243. For matriculation, students must be graduates of collegiate institutions of recognized standing or seniors in absentia, who will receive the bachelor degree from their college after having completed successfully at least one year of work in the school of medicine. The course covers four years of nearly nine months each. The total fees are, respectively, \$465, \$465, \$465 and \$470. The registration for 1940-1941 was 206; graduates, 54. The next session begins Sept. 22, 1941, and ends June 10, 1942. The Dean is Waller S. Leathers, M.D.

TEXAS

Dallas

BAYLOR UNIVERSITY COLLEGE OF MEDICINE, 810 College Avenue.—Organized in 1900 as the University of Dallas Medical Department. In 1903 it took its present name and became the Medical Department of Baylor University. It acquired the charter of Dallas Medical College in 1904. Coeducational since organization. The first class graduated in 1901. The faculty consists of 119 professors and 112 instructors and assistants, a total of 231. Entrance requirements are three years of collegiate work. The course covers four years of eight months each. The fees are, respectively, \$419, \$409, \$399 and \$424. The registration for 1940-1941 was 306; graduates, 64. The next session begins Sept. 29, 1941, and ends June 1, 1942. The Dean is W. H. Moursund, M.D.

Galveston

UNIVERSITY OF TEXAS MEDICAL BRANCH, 912 Avenue B. Organized in 1891. The first class graduated in 1892. Coeducational since organization. It has a faculty of 40 professors and 107 instructors and assistants, a total of 147. Beginning with the 1941-1942 session the curriculum was changed to the four quarter plan, each quarter lasting eleven weeks. The total fees are, respectively, \$46, \$27, \$39 and \$37. Included

in this is a matriculation fee of \$17 per quarter. The registration for 1940-1941 was 382; graduates, 85. During 1941-1942 the quarters begin June 16, Oct. 1, Jan. 2 and March 26 and end Aug. 31, Dec. 20, March 19 and June 9. The Dean is John W. Spies, M.D.

VERMONT Burlington

UNIVERSITY OF VERMONT COLLEGE OF MEDICINE, Pearl Street, College Park.—Organized with complete course in 1822. Classes graduated in 1823 to 1836, inclusive, when the school was suspended. It was reorganized in 1853 and classes were graduated in 1854 and in all subsequent years. Coeducational since 1920. It has a faculty of 64 professors and 54 instructors, and assistants, a total of 118. Three years of collegiate work are required for admission. The course of study covers three years of nine months each and a fourth year of eleven months. For residents of Vermont the tuition fee is \$400 each session. Nonresidents are charged an additional \$150 each session. A \$25 fee is charged for the doctor's degree. The registration for 1940-1941 was 124; graduates, 31. The next session begins Sept. 19, 1941, and ends June 15, 1942. The Chairman of the Administrative Committee is Clarence H. Beecher, M.D.

VIRGINIA Charlottesville

UNIVERSITY OF VIRGINIA DEPARTMENT OF MEDICINE.—Organized in 1827. Classes were graduated in 1828 and in all subsequent years except 1865. Coeducational since the session of 1920-1921. It has a faculty of 45 professors and 41 lecturers, instructors, assistants and others, a total of 86. Three years of college work are required for admission. For residents of Virginia the total fees are, respectively, \$419, \$401, \$366 and \$366. Nonresidents are charged an additional \$50 each year. The registration for 1940-1941 was 250; graduates, 54. The next session begins Sept. 18, 1941, and ends June 15, 1942. The Dean is Harvey Ernest Jordan, Ph.D.

Richmond

MEDICAL COLLEGE OF VIRGINIA, Twelfth and Marshall Streets.—Organized in 1838 as the Medical Department of Hampden Sydney College. Present title was taken in 1854. In 1913 the University College of Medicine was merged. In 1914 the North Carolina Medical College was merged. Coeducational since 1918. Classes were graduated in 1839 and in all subsequent years. It has a faculty of 81 professors and 147 lecturers, instructors and others, a total of 228. Three years of collegiate work are required for admission. The course covers four years of eight and one-half months each. Total fees are, respectively, \$379, \$379, \$379 and \$381. Nonresidents are charged an additional \$125 each year. The registration for 1940-1941 was 295; graduates, 74. The next session begins Sept. 2, 1941, for the first year class; Sept. 15, 1941, for all other classes, and ends June 2, 1942. The Dean is Lee E. Sutton Jr., M.D.

WISCONSIN

Madison

UNIVERSITY OF WISCONSIN MEDICAL SCHOOL, 408 North Charter Street.—Organized in 1907. Gave only the first two years of the medical course until 1925, when the clinical years were added. Coeducational since organization. Three years of collegiate work are required for admission. The B.S. degree in medical science is conferred at the end of the first year. It has a faculty of 64 professors and 67 lecturers, instructors and others, a total of 131. The fees are, respectively, \$222, \$212, \$182 and \$120. An additional fee of \$200 each year is charged nonresidents. The registration for 1940-1941 was 258; graduates, 48. The next session begins Sept. 24, 1941, and ends June 22, 1942. The Dean is William S. Middleton, M.D.

Milwaukee

MARQUETTE UNIVERSITY SCHOOL OF MEDICINE, 561 North Fifteenth Street.—Organized in December 1912, by the merger of the Milwaukee Medical College and the Wisconsin College of Physicians and Surgeons. Coeducational since organization. It has a faculty of 173. Three years of collegiate work are required for admission. The curriculum covers four years of eight and a half months each, and one year's internship in an approved hospital. The fees are as follows: first year, \$462; second year, \$450; third year, \$450; fourth year, \$400. The registration for 1940-1941 was 312; graduates, 72. The next session begins Sept. 29, 1941, and ends June 10, 1942. The Dean is Eben J. Carey, M.D.

CANADA

Alberta

UNIVERSITY OF ALBERTA FACULTY OF MEDICINE, Edmonton.—Organized in 1913. Coeducational since organization. Has given the complete six-year medical course since 1924. The Faculty includes 23 full time and 45 part time professors, instructors, assistants and others, a total of 68. Tuition for the second, third and fourth years is \$215, for the fifth and sixth years \$225. The registration for 1940-1941 was 201; graduates, 37. The next session begins Sept. 26, 1941, and ends April 10, 1942. Special session advancement of graduating class only, for military service, begins July 2, 1941, ends Feb. 28, 1942. The Acting Dean is John James Ower, M.D.

Manitoba

UNIVERSITY OF MANITOBA FACULTY OF MEDICINE, Bannatyne Avenue, Winnipeg. Organized in 1883 as Manitoba Medical College; first class graduated in 1886, and a class graduated each subsequent year. The

college transferred all its property to the University of Manitoba in 1919 and assumed the present title. Coeducational since organization. The faculty includes 26 professors and 80 instructors and assistants, a total of 106. Matriculation requirements include two years of collegiate work in the faculty of arts and science of a recognized university. The course extends over four years of eight months each and a hospital internship. The total fees are, respectively, \$298, \$293, \$303, \$303, \$77. The registration for 1940-1941 was 217; graduates, 62. The next session begins Sept. 12, 1941, and ends May 13, 1942. The Dean is A. T. Mathers, M.D.

Nova Scotia

DALHOUSIE UNIVERSITY FACULTY OF MEDICINE, Morris Street, Halifax.—Organized in 1867. Incorporated as the Halifax Medical College in 1875. Reorganized as an examining faculty, separate from the Halifax Medical College, in 1885. In 1911, in accordance with an agreement between the Governors of Dalhousie University and the Corporation of the Halifax Medical College, the work of the latter institution was discontinued and a full teaching faculty was established by the university. First class graduated in 1872. Coeducational since 1871. It has a faculty of 32 professors and 27 demonstrators, lecturers and others, a total of 59. Requires for matriculation two years of arts. The medical course covers four years and a hospital internship of one year. The fees are \$317, \$322, \$317, \$307 and \$307 for each year, respectively; \$250 additional registration fee payable by students outside the British Empire. The registration for 1940-1941 was 177, graduates, 41. The next session begins Sept. 9, 1941, and ends May 12, 1942. The Dean is H. G. Grant, M.D.

Ontario

QUEEN'S UNIVERSITY FACULTY OF MEDICINE, Kingston.—Organized 1854, first class graduated in 1855, and a class graduated each subsequent year. The faculty numbers 60. The fee for the first year is \$233 and \$255 for each of the other five years. The course covers six years of thirty teaching weeks each. The registration for 1940-1941 was 266; graduates, 42. The next session begins Sept. 25, 1941, and ends May 15, 1942. The Dean is Frederick Etherington, M.D.

UNIVERSITY OF TORONTO FACULTY OF MEDICINE, Toronto.—Organized in 1843 as the Medical Faculty of King's College. Abolished in 1853. Reestablished in 1887. In 1902 it absorbed Victoria University Medical Department, and in 1903 it absorbed the Medical Faculty of Trinity University. Coeducational since 1903. The course of study covers six years of eight months each. The B.Sc. (Med.) degree is conferred at the end of the third or sixth year. It has a faculty of 83 professors and 337 lecturers, associates and others, a total of 420. The fees are \$226 for the first year; for the second, \$389; \$296 for the third year, \$321 for the fourth and fifth years, and \$353 for the sixth year. The registration for 1940-1941 was 747; graduates, 138. As there is a shortage of doctors in Canada, both for the armed forces and for civilian needs, the duration of the academic session of the Faculty of Medicine, University of Toronto, has been increased to ten months extending from Aug. 25, 1941, to June 27, 1942. The final year class will graduate in April, 1942 and every eight months thereafter. The next session begins Aug. 25, 1941, and ends June 27, 1942. The Dean is W. E. Gallie, M.D.

UNIVERSITY OF WESTERN ONTARIO MEDICAL SCHOOL, Orlow Avenue, London.—Organized in 1881 as the Western University Faculty of Medicine; first class graduated in 1883, and a class graduated each subsequent year. Present title in 1923. The medical school has been under the control of the Board of Governors of the University of Western Ontario since 1913. Coeducational since 1913. The faculty numbers 89. The course of study covers six years of eight months each. The total fees to residents of Canada for the last four years, respectively, are \$349, \$345, \$353 and \$291; nonresidents are charged \$637, \$633, \$641 and \$516 for each of the last four years. The registration for 1941-1942 was 222; graduates, 30. Owing to war conditions, the next session begins for the sixth year July 2, 1941, and ends Feb. 28, 1942. Classes for the second, third, fourth and fifth years begin Aug. 25, 1941, and end June 27, 1942. The Dean is F. J. H. Campbell, M.D.

Quebec

LAVAL UNIVERSITY FACULTY OF MEDICINE, Quebec.—The Quebec School of Medicine, organized in 1848, became in 1852 the Laval University Faculty of Medicine; first class graduated in 1855, and a class graduated each subsequent year. The faculty numbers 89. The fees for each of the medical years are \$175 for residents of Canada. Nonresidents are charged an extra fee of \$175 each year. The premedical requirement is a B.A. degree or its equivalent. The registration for 1940-1941 was 315; graduates, 69. The next session begins Sept. 10, 1941, and ends May 30, 1942. The Dean is Charles Vézina, M.D.

MCGILL UNIVERSITY FACULTY OF MEDICINE, 3640 University Street, Montreal.—Founded in 1823 as Montreal Medical Institution; became the Medical Faculty of McGill University in 1829; first class graduated under the university auspices in 1833. No session between 1836-1839, owing to political troubles. In 1905 it absorbed the Faculty of Medicine of the University of Bishop's College. Coeducational since 1919. Three years of collegiate work are required for admission. The M.D. is conferred upon the completion of four sessions of 36 teaching weeks. The faculty consists of 58 professors and 183 lecturers and others, a total of 246. The total fee for each of the four medical years are \$391 plus \$100 for non-British subjects. The registration for 1940-1941 was 385; graduates, 89. The next session begins Sept. 3, 1941, and ends May 31, 1942. The Dean is J. C. Meakins, M.D.

UNIVERSITY OF MONTREAL FACULTY OF MEDICINE, 1265 St Denis Street, Montreal—Organized in 1843 as the Montreal School of Medicine and Surgery. In 1891, by Act of Parliament, the Medical Faculty of Laval University (organized in 1878) was absorbed. Present name by Act of Parliament in 1920. A class was graduated in 1843 and each subsequent year. Coeducational since 1925. The faculty numbers 140. The

BA or BS degree, or its equivalent, is a prerequisite to the premedical year, which precedes a five year medical course, the fifth year being a compulsory internship year. The total fees for each of the five years respectively are \$245, \$229, \$271, \$235, \$218. The registration for 1941-1942 was 203, graduates, 54. The next session begins Sept 13, 1941, and ends June 15, 1942. The Dean is Albert LeSage, M.D.

DESCRIPTION OF SCHOOLS OF THE BASIC MEDICAL SCIENCES

ALABAMA

University (Tuscaloosa)

UNIVERSITY OF ALABAMA SCHOOL OF MEDICINE—Organized in 1859 at Mobile as the Medical College of Alabama. Classes graduated in 1861 and subsequent years excepting 1862 to 1868, inclusive. Reorganized in 1897 as the medical department of the University of Alabama. Present title assumed in 1907, when all property was transferred to the University of Alabama. In 1920 clinical teaching was suspended and the medical school was removed to the university campus near Tuscaloosa. Coeducational since 1920. Minimum entrance requirements are three years of collegiate work. The course of study covers two years of thirty-six weeks each. The faculty includes 15 professors and 14 instructors, assistants, and others, a total of 29. The tuition fees are \$301 each year plus \$75 differential for nonresidents. Each class is limited to fifty students. The registration for 1940-1941 was 101. The next session begins Sept 10, 1941, and ends May 27, 1942. The Dean is Stuart Graves, M.D.

MISSISSIPPI

University

UNIVERSITY OF MISSISSIPPI SCHOOL OF MEDICINE—Organized in 1903. Coeducational since organization. Gives only the first two years of the medical course. A clinical department was established at Vicksburg in 1908 but was discontinued in 1910 after graduating one class. The session extends over eight and one-half months. Entrance requirement is three years of collegiate work. The BS degree in medicine is conferred at the end of the second year. The faculty includes 8 professors, 2 assistant professors, 1 associate professor, 1 adjunct professor, 20 instructors, assistants and others, a total of 32. The total fees for the first year are \$353, and for the second year \$325. The nonresident fee is \$50 additional each year. The registration for 1940-1941 was 46. The next session begins Sept 18, 1941, and ends June 1, 1942. The Dean is B. S. Guyton, M.D.

MISSOURI

Columbia

UNIVERSITY OF MISSOURI SCHOOL OF MEDICINE—Organized at St. Louis in 1845, was discontinued in 1855 but was reorganized at Columbia in 1872. Teaching of the clinical years was suspended in 1909. Coeducational since 1872. The faculty includes 21 professors and 14 instructors, lecturers and others, a total of 35. The entrance requirements are 90 semester hours of collegiate work. The BS degree in medicine is conferred at the end of the second year. Total fees for the first year are \$191, for the second, \$177. The registration for 1940-1941 was 83. The next session begins Sept 15, 1941, and ends June 12, 1942. The Dean is Dudley S. Conley, M.D.

NEW HAMPSHIRE

Hanover

DARTMOUTH MEDICAL SCHOOL—Organized by Dr. Nathan Smith in 1797. The first class graduated in 1798. It is under the control of the trustees of Dartmouth College. Courses of the third and fourth year were discontinued in 1914. The faculty consists of 21 professors and 11 instructors, a total of 32. Three years of collegiate work and candidacy for the bachelor's degree are required for admission. The course covers nine calendar months in each year, or eight months of actual teaching. Candidates for the A.B. degree in Dartmouth College may substitute the work of the first year in medicine for that of the senior year in the academic department. The tuition is \$450 for each year. The registration for 1940-1941 was 41. The next session begins Sept 17, 1941, and ends June 14, 1942. The Dean is John P. Bowler, M.D.

NORTH CAROLINA

Chapel Hill

UNIVERSITY OF NORTH CAROLINA SCHOOL OF MEDICINE—Organized in 1890. Until 1902 this school gave only the work of the first two years, when the course was extended to four years by the establishment of a department in Raleigh. The first class graduated in 1903. A class was graduated each subsequent year, including 1910 when the clinical department at Raleigh was discontinued. Coeducational since 1914. A minimum of three years of college work is required for admission. Certificates are awarded on the completion of the two years' work in medicine. The faculty is composed of 16 professors and 13 instructors, a total of 29. The fees for each year are \$300 for residents, for nonresidents an additional fee of \$100. The registration for 1940-1941 was 78. The next session begins Sept 23, 1941, and ends June 9, 1942. The Acting Dean is W. Reece Berryhill, M.D.

Winston-Salem

WAKE FOREST COLLEGE SCHOOL OF MEDICAL SCIENCES formerly at Wake Forest, N. C. has been moved to Winston-Salem, N. C. and will hereafter be known as the BOWMAN GRAY SCHOOL OF MEDICINE OF

WAKE FOREST COLLEGE. Organized in 1902 as a part of Wake Forest College. The Board of Trustees has authorized the extension of the curriculum to include four years of instruction leading to the degree of doctor of medicine. The new plant in Winston-Salem is under the care of as the North Carolina Baptist Hospital. The faculty numbers 22 professors and 80 assistant professors, instructors, assistants and lecturers making a total of 102. Ninety semester hours of college work are required for admission. The BS degree is given after the completion of the first year to those not already holding that degree. Each academic year extends over nine months. Tuition for each academic year is \$100. Registration for the year 1940-1941 was 66. The next session begins Sept 10, 1941, and ends June 1, 1942. The Dean is C. C. Carpenter, M.D.

NORTH DAKOTA

Grand Forks

UNIVERSITY OF NORTH DAKOTA SCHOOL OF MEDICINE—Organized in 1905. Offers only the first two years of the medical course. Coeducational since organization. Three years' work in a college of liberal arts is required for admission. The BS degree in combined arts and medical course is conferred at the end of the second year. The faculty consists of 8 professors and 8 instructors, a total of 16. The fees are \$80 each year for resident students and \$165 for nonresidents. The registration for 1940-1941 was 47. The next session begins Sept 16, 1941, and ends June 9, 1942. The Dean is H. E. French, M.D.

SOUTH DAKOTA

Vermillion

UNIVERSITY OF SOUTH DAKOTA SCHOOL OF MEDICAL SCIENCES—Organized in 1907 as the University of South Dakota School of Medicine. Present title in 1937. Coeducational since organization. Offers only the first two years of the medical course. Three years' work in a college of liberal arts is required for admission. Students who complete the third year of premedical work in the College of Arts and Sciences at the University of South Dakota may apply the work of the first year of medicine to the A.B. degree. The BS degree is conferred at the end of the second year on those students who do not hold a combination (Arts and Sciences and Medicine Course) A.B. degree. The faculty numbers 18. The tuition is \$150 each year for residents and \$250 for nonresidents. The registration for 1940-1941 was 45. The next session begins Sept 18, 1941, and ends June 8, 1942. The Dean is Joseph C. Ohlmacher, M.D.

UTAH

Salt Lake City

UNIVERSITY OF UTAH SCHOOL OF MEDICINE, University Street—Organized in 1906. Coeducational since organization. Gives only first two years of medical course. Each school year covers thirty-six weeks. Three years of collegiate work are required for admission. The medical faculty consists of 11 professors, 1 instructor, 21 lecturers and demonstrators, and 5 fellows, assistants, and technicians, a total of 38. The fees for each year are \$229. There is a nonresident fee of \$75 each year. The registration for 1940-1941 was 63. The next session begins Sept 29, 1941, and ends June 5, 1942. The Dean is L. L. Daines, M.D.

WEST VIRGINIA

Morgantown

WEST VIRGINIA UNIVERSITY SCHOOL OF MEDICINE—Organized in 1902, gives the first two years of the medical course. Coeducational since organization. Three years of collegiate work are required for admission. The BS degree in medicine is conferred at the end of the second year. Session extends through nine months. Faculty numbers 24. Fees for residents of the state are, respectively, \$254 and \$264; nonresidents \$150 additional each year. The registration for 1940-1941 was 45. The next session begins September 18, 1941, and ends June 8, 1942. The Dean is Edward J. Van Lier, M.D.

CANADA

Saskatchewan

UNIVERSITY OF SASKATCHEWAN SCHOOL OF MEDICAL SCIENCES Saskatoon—Organized in 1926. Coeducational. Offers the first two years of the medical course. Two years of collegiate work are required for admission. The BA degree is conferred at the end of the second year. The medical faculty includes 7 professors and 4 lecturers and assistants, a total of 11. The fees are \$150 for each year. The registration for 1940-1941 was 49. The next session begins Sept 22, 1941, and ends May 8, 1942. The Dean is W. S. Lindsay, M.D.

GRADUATE MEDICAL EDUCATION

Internships and Residencies

The work of the Council in the field of internships and residencies is commented on at length in the Hospital Number of THE JOURNAL.¹ Two very timely subjects are presented in this issue because of their current interest.

NECROPSY PERFORMANCE

The list of hospitals approved for intern training which achieved the commendable record of necropsies in 70 per cent or more of their cases of death is

Hospitals in Which Necropsies Exceeded Seventy per Cent of Fatalities

presented herewith. It will be noted that the list contains the names of forty institutions, an increase of eleven over the previous high reported in 1940.² It

Continuation Study for Practicing Physicians in the United States, 1940-1941

Since 1937 the Council on Medical Education and Hospitals has been actively engaged in the collection of information on the facilities available throughout the United States for continuation study. Progress reports on this survey appeared in the Educational Number of THE JOURNAL of 1938,³ 1939⁴ and 1940.⁵ A review of the developments and of the accomplishments in this phase of graduate medical education was published in composite form by the Council in May 1940.⁶ The

is especially gratifying that small as well as large institutions have manifested this interest in educational work and that the list includes non-tax supported as well as public hospitals. In the group are institutions which are, not connected with medical schools and also hospitals sponsored by various religious denominations.

INTERNS AND RESIDENTS ENTERING MILITARY SERVICE 1940-1941

Late in June and early in July of this year the Council sent a questionnaire to one thousand and forty-three hospitals approved for intern training, residency training or both. All approved hospitals except those operated by the Army and Navy were included. Returns were received from nine hundred and seventy institutions, or 93 per cent. The questions concerned the induction of interns and residents into active military service by order of local Selective Service boards and the interns and residents holding commissions in the Medical Reserve Corps of the Army and Navy who were called to active duty. A study of the returns indicates the following:

1. Only two graduates were inducted by order of Selective Service boards before completing at least one year of intern training.

2. Up to July 1, 1941 two hundred and seventy-eight interns and five hundred and sixty-nine residents holding commissions in the reserve corps entered the military service before the completion of their current hospital appointments.

3. Comments by hospital superintendents led to the belief that all medical graduates called up by Selective Service boards were given an opportunity to apply for commissions in the Medical Reserves of the Army or Navy.

4. According to the annual reports received from hospitals in January 1941 there were on duty in approved internship and residency hospitals 7,553 interns and 5,247 residents. These figures include women graduates and also men serving in army and navy hospitals.

5. From these data it appears that the preparedness program has not yet had as marked an effect on the house staffs of hospitals as might have been expected. However, hospitals probably will encounter increasing difficulty in maintaining their intern and resident staffs.

opportunities for continuation study have been reviewed again for the year 1940-1941 and are presented in the present report.

As a result of the Council's survey the Principles Regarding Graduate Medical Schools adopted in 1923 were revised by the Council on June 11, 1940 and approved by the House of Delegates. The need was recognized for adequate clinical facilities where physicians who do not limit their practice to a specialty may find ample opportunity to learn by personal examination of patients and by conduct of essential laboratory tests. The progressive grading of courses which would provide continuity of instruction as part of a systematic program over the years was emphasized. Institutions

(Continued from page 709)

which offer courses leading to restricted practice in a specialty have greater responsibilities than formerly, and these have been outlined in the newly adopted set of principles.

This year, for the first time, the Council is gathering data on proposed courses, and it is contemplated that publication of this information will be made at periodic intervals for ready reference in *THE JOURNAL*. The institutions conducting graduate programs and their location, the date when instruction begins, the length and content of the courses, the type of instruction offered, the number of physicians accepted for each course and their eligibility, the instructors participating and the fees required will be included. Courses restricted to intramural postgraduate education in obstetrics and pediatrics designed for practicing physicians recently were summarized briefly, such courses being financed in whole or in part from social security funds.⁷

RECENT DEVELOPMENTS IN STATE AND LOCAL PROGRAMS

The Associated State Postgraduate Committees held their fifth annual meeting at Cleveland on June 4, 1941. It was the suggestion of Dr. Henry H. Turner of Oklahoma that a national registry of postgraduate assemblies and a registry for postgraduate instructors be established. A committee is to be appointed to study the proposal and to present a resolution on this subject at the next annual meeting of the House of Delegates.

The University of California Medical School, San Francisco, now serves as a center for postgraduate education in pediatrics and obstetrics for the states of California, Nevada, Utah, Idaho, New Mexico and Arizona. Funds are supplied from participating states, the Rosenberg Foundation and the Children's Bureau of the U. S. Department of Labor.

During January 1941 a three day refresher course in the clinical aspects of dermatology was given for practicing physicians at the University of California Medical School, San Francisco. A fee of \$20 was charged. During June 1941 a week of instruction in general medicine, including the fields of heart disease, diseases of the blood, gastroenterology and endocrinology, and a one week course in general surgery, including traumatic surgery, fractures, treatment of infections and hand injuries, was given. Each program was designed for practicing physicians.

From January to April 1941 the Committee on Clinical Congress of the Connecticut State Medical Society organized two courses of fourteen lectures each given at weekly intervals in the Yale University School of Medicine on diseases of nutrition and on industrial medicine. A registration fee of \$3 was charged for each course.

In Georgia, postgraduate courses conducted by the state medical association were inaugurated during the past year. One week courses in general medicine and surgery were given at Waycross and at Albany. These seminars were financed by an appropriation of the medical association. In the future a small registration fee will be charged.

A five weeks postgraduate course in obstetrics was offered during 1940-1941 to practicing physicians by the University of Chicago and the Chicago Lying-in Hospital in cooperation with the Illinois State Depart-

ment of Health and the Children's Bureau of the United States Department of Labor. The number of registrants was limited to five for each course. A registration fee of \$15 was charged.

The medical school of the State University of Iowa, Iowa City, established a one week course in obstetrics during 1940-1941. Only three physicians were accepted each week; no registration fee was charged. The Division of Maternal and Child Health of the State Department of Health cooperated.

The Department of Graduate Medicine, School of Medicine, Tulane University of Louisiana, New Orleans, offered a course in tropical medicine and medical parasitology to physicians during 1940-1941. Instruction in the etiology, epidemiology, pathology, symptomatology, diagnosis, treatment and control of diseases of warm climates was included during four and one-half months. Physicians from Latin America were enrolled as well as those from other countries. A registration fee of \$300 was charged and clinical pathologic equipment was provided by each registrant.

The chairman of the committee on graduate education, Dr. F. T. Hill of the Maine Medical Association, has reported that, while only 10 per cent of physicians continue their education independently, 73 per cent attend hospital staff meetings regularly. This fact suggests the more efficient use of hospital facilities in any program of postgraduate study. Staff meetings with case studies as a basis of the program with a clinical pathologic presentation, panel discussions and the participation of guest speakers have proved especially effective in Maine.

The Massachusetts Medical Society in cooperation with the state department of health and the U. S. Public Health Service planned to provide a medical library extension service in connection with the state society's program of postgraduate education. The Boston Medical Library was charged with the operation and with the establishment of the loan service. Funds were provided by the U. S. Public Health Service.

The Medical Association of Montana has joined the four other state societies of Colorado, New Mexico, Utah and Wyoming in the Rocky Mountain Medical Conference. The 1941 conference is scheduled to be held in the Yellowstone National Park, September 2 to 4.

At the Continuation School of Medicine, Detroit, under the joint auspices of the Wayne County Medical Society and the Wayne University College of Medicine a course in industrial medicine and surgery was given for the first time during 1940-1941. Fifty-three enrolled for the lectures, illustrated by lantern slides and movies.

The Committee on Post-Graduate Education of the Medical Society of New Jersey has affiliated with the New York University College of Medicine for the purpose of organizing clinical teaching in the Newark City Hospital. Six to nine weeks refresher courses with two or three hour sessions each week for groups of from four to twenty physicians were planned to permit close supervision and instruction and have been conducted during 1940-1941. Subjects included were peripheral vascular diseases, fractures, diseases of the liver and biliary tract, amputations and tuberculosis. Teaching at the bedside was emphasized. Tuition of \$20 or \$25 was charged.

The New York University College of Medicine has organized similar courses for the practicing physicians of Queens County, N. Y. Subjects included for this group were diagnostic roentgenology, internal medicine,

7. Daily, E. F.: Intramural Postgraduate Education in Obstetrics and Pediatrics, *J. A. M. A.* 115:1436 (Oct. 26) 1940.

varicose veins and dermatology. Courses were given in the clinics and wards of the Queens General Hospital, each consisting of a two hour session weekly for five to ten weeks. Case teaching methods were employed, and in the course in internal medicine each registrant had the opportunity to demonstrate the various methods of diagnosis. Fees varied from \$25 to \$50; from six to ten students were accepted for each course.

At Duke University School of Medicine, Durham, N. C., a course in obstetrics and pediatrics was organized during 1940-1941. Registration was limited to four physicians practicing in the state. A \$15 fee was charged, which was returned on completion of the course. The maternal and child health service division of the state board of health cooperated in providing meals and lodging for registrants. Instruction was of an informal, clinical and practical nature.

The Northwest Texas Medical Association held its first postgraduate assembly at Marshall, Texas, on Dec. 5, 1940. The program was presented by members of the staff of Baylor University College of Medicine. There were ten hours of lectures and round table discussions. A \$1 registration fee was charged.

A speakers' bureau has been established by the Postgraduate Medical Education Committee of the Washington State Medical Association. Eighty-eight Washington physicians comprise the bureau. Subjects included those sponsored by the state department of health. In addition, a plan has been devised for groups of five out of state speakers to give lectures and clinics in obstetrics and gynecology, pediatrics, surgery, medicine, traumatic surgery and fractures. These lectures, designed primarily for practicing physicians, are to be given in a central location in five districts of the state, with one afternoon and evening meeting at local hospitals for five consecutive weeks.

RECENT DEVELOPMENTS IN NATIONAL PROGRAMS

Under the joint auspices of the Pan American Sanitary Bureau and the United States Public Health Service twenty-one fellowships have been awarded to young medical graduates of thirteen countries of South and Central America during 1940-1941. They were distributed as follows: Argentina two, Bolivia one, Brazil two, Colombia three, Chile one, Costa Rica one, Cuba one, Ecuador four, Guatemala two, Haiti one, Honduras two, Mexico one and Peru one. These fellows were assigned to teaching or research institutions in New York, Massachusetts, Maryland, Michigan, Pennsylvania, Illinois, Missouri, Virginia, Louisiana and the District of Columbia.

The number of creditable applications for intern training and graduate study from physicians of Latin America is increasing. For this reason additional funds have been provided by the coordinator of commercial and cultural relations among the American republics for financing additional fellowships for the year 1941-1942. At least thirty-five additional fellows are to be selected and placed during the coming year.

The American Foundation for Tropical Medicine, Inc., has established a limited number of fellowships for postgraduate study in tropical medicine at Tulane University of Louisiana School of Medicine, New Orleans. These fellowships are available to qualified physicians of Central and South America and Mexico. Tuition fees are paid by the foundation as well as travel and maintenance not to exceed \$700. The United States Department of State, Washington, D. C., aids

in publicizing this graduate study, which is confined largely to the diagnosis and management of diseases of warm climates.

From July 1940 to June 1941 one thousand, one hundred and seventy-five applications for instruction in public health were received by state health departments. Approximately 28 per cent of the applicants were physicians. The United States Public Health Service approved such applications as well as budgets of state health departments and of schools which offered post-graduate public health training.

Three types of training were provided: academic study, college or university accredited field training and nonaccredited field practice, which included supervised experience in clinics and hospitals. The first and third types were each selected by about half of the applicants. The duration of training varied from less than one month to twelve months.

Applications were received from physicians of thirty-eight states and Puerto Rico. Johns Hopkins University, Vanderbilt University, Harvard University, University of Michigan, University of North Carolina, University of Minnesota and Columbia University received the greatest number of graduate students in public health under this program, while ten physicians applied to other institutions.

The United States Army Medical School, Washington, D. C., provided during 1940-1941 a condensed basic graduate course of one month's duration for medical officers. Professional specialists' courses of varying duration were continued during 1940 and until March 1, 1941, when they were discontinued except for informal training. After approximately six months' duty, Reserve and National Guard Medical Department officers may be afforded an opportunity to attend a one month refresher course at the Medical Field Service School or at certain general hospitals. A course in tropical medicine for medical officers has been authorized. This instruction will be given over four weeks and will be repeated each month. It is contemplated that the first class will begin about Aug. 1, 1941. Enrollment will be limited to approximately thirty men.

During 1940-1941 the Bureau of Medicine and Surgery, Navy Department, Washington, D. C., provided six weeks of instruction for thirty-one assistant surgeons of the United States Navy. The general subject was military medicine, with special instruction in the medical aspects of air raid precautions, atmospheric hygiene, aviation medicine, chemical warfare and damage control, as well as neuropsychiatry and other subjects commonly included in the study of medicine. Beginning in August 1941 a class of fifty medical officers of the Navy will assemble at the Naval Medical School, Naval Medical Center, Washington, D. C., for a similar course of instruction.

The United States Department of Labor, Children's Bureau, Washington, D. C., continues to provide funds for the postgraduate education of practicing physicians. Thirty-six states were aided and more than two hundred communities were affected. Registration for extramural refresher courses exceeded six thousand physicians, and for intramural courses given in medical schools more than five hundred physicians registered.

The American College of Physicians offered, for the fourth year, ten courses in special subjects for members of the college and for physicians preparing for certification by the American Board of Internal Medicine. For the first time instruction was given during the

1. Medical manager or similar official offered physicians taking these courses
2. Courses offered on request of the College or for those preparing (either to meet requirements for membership in the College or certification by the American Board of Internal Medicine)
3. Free to any member of state medical society recommended by Chairman of National Welfare Committee.

(Continued from page 713)

midwinter of 1940-1941. The committee on postgraduate courses of the college has outlined the following principles:

1. Intensive courses of two weeks' duration are most in demand.
2. Similar subjects should be given in alternate years at different institutions and localities.
3. Instruction should be organized at an appropriate level for the physicians registered.
4. The needs of the registrants should be known and the course planned accordingly.
5. Instructors should be fully qualified men of experience.

The American Academy of Ophthalmology and Otolaryngology has continued courses of instruction at the annual meetings of the academy. In August 1940 home study courses, through directed reading, in the fundamentals of ophthalmology and otolaryngology were started. These courses were intended primarily for residents in institutions which gave no formal instruction. In addition to this group, physicians preparing for certification and those practicing in smaller communities registered for the study course. A total of four hundred and sixty-five physicians subscribed, paying a fee of \$10 each.

The course was conducted as follows: Each month reading assignments in standard textbooks were given which would require between one and one and a half hours' study daily. At the end of each month twenty questions covering the assignments of the preceding month were sent to each registrant, answered, and then returned to the committee of the academy. Different groups of ophthalmologists and otolaryngologists over the country corrected the answers and graded the examinations and returned them to the registrants. Subjects included in the course were anatomy, histology, embryology, physiology, bacteriology, pathology, and biochemistry of the eye, ear, nose and throat, refraction, perimetry, optics, biomicroscopy, and hearing and vestibular tests. This course will be repeated beginning Aug. 1, 1941.

CONTINUATION STUDY FOR PRACTICING PHYSICIANS, 1940-1941

Opportunities provided for practicing physicians during the fiscal year ending July 1, 1941 are outlined in tables 1-A, pages 710-711; 1-B, pages 714-720, and table 2, pages 722-725. Courses reported in table 1-A were of a peripatetic character in that instruction was offered to the practicing physician in a number of different places in or near his local community. Centers listed in table 1-B provided ample facilities for clinical instruction. In the first type of course the instructors usually do most of the traveling, while in the latter the physician desiring continuation study frequently travels to the center where clinical teaching may be emphasized over longer periods.

ORGANIZATION AND ADMINISTRATION

Opportunities for continuing professional study for practicing physicians near their home communities held a prominent place in twenty-eight states. These programs reached a total of three hundred and eight towns. In four other courses given over the state, the number of centers was not reported. Of thirty-one sponsoring agencies, committees on postgraduate education of state medical societies, independently or with the department of health or university, supervised twenty-three programs. State health departments were active partici-

pants in sixteen courses, the extension divisions of five universities and four state tuberculosis and public health associations cooperated in bringing programs to the practitioner.

In centers where ample clinical facilities are available (table 1-B) graduate courses of less than one year's duration were offered in seventy-six centers located in thirty-three states and the District of Columbia. Ninety-nine agencies or combinations of agencies in forty states participated in the planning of programs, although courses sponsored by ten state agencies were given outside the state.

Of the medical schools of the country, forty-seven have given courses for practicing physicians during the past year, including six postgraduate schools or graduate departments of medical schools. Twenty-four health departments and nineteen state medical societies collaborated with the health departments or independently planned courses for the physicians of the state. In eleven instances hospitals were the agencies offering short periods of study. Other sponsors included five county medical societies, two academies of medicine, two universities not having medical departments, a clinical society, a national society and an institute of technology.

In medical school programs the deans were indicated as directing officer of about one half of the postgraduate courses. The head or a member of the department in which the study is offered often directed the course. Chairmen of postgraduate educational committees in universities and of medical associations, directors of departments of health and the chief of staff of several hospitals acted as administrators.

METHODS OF INSTRUCTION

Opportunities for instruction in obstetrics and pediatrics were prominent among the courses for physicians continuing professional study near their homes. Programs covering the general subjects of medicine and surgery were available in fourteen distinct areas, obstetrics and pediatrics in twelve, tuberculosis and communicable diseases in six and special subjects such as dermatology and syphilology, heart disease and cancer in six. Instruction was given at weekly intervals in fifteen of these courses, the number of classes varying from two to ten. Two courses were scheduled for six evenings and one for a period of from five to six days. One day programs for practitioners were arranged in nine of the courses. In addition to lectures and round table discussions, all but eight of the courses for physicians in their own communities were planned to include clinics, symposiums, demonstrations and conferences. Public buildings were utilized for lectures and discussion groups, and the facilities of hospitals were used for supplementary practical instruction in all but nine programs. The traveling faculties for these extramural courses were chosen about equally from within the state sponsoring the course and from an out of state position. Of these instructors, 80 per cent were from the faculties of medical schools.

The descriptions of all intensive courses gave evidence that clinical instruction was featured. The study of general medical subjects or the specialties was offered in various combinations by one third of the medical centers. In the specialty group, ophthalmology, otolaryngology, cardiology and syphilology appeared in the reports most often. Other special topics of study included allergy, aviation medicine, bronchoscopy, electrocardiology, endocrinology, esophagology, gastroscopy,

1. Stipend to cover registration fees and per diem expense.

gynecology, hematology, industrial medicine, infections, metabolism, physical therapy, modern therapy, nutrition, orthopedics, peripheral vascular diseases, parasitology, psychology, psychiatry, public health, radiology, silicosis, tropical medicine, tuberculosis, urology and venereal disease. Special courses not enumerated were also available at eighteen medical schools and universities. Courses in preclinical subjects were recorded on only nine questionnaires.

The duration of study in centers with clinical facilities varied from five days to one year. Sixty-one courses were completed within three weeks or less, while eighteen lasted a month or more. In seven medical centers, enrolment for periods of from one week to a year was possible depending on the course length. Nine centers had no available courses of less than a month, the duration varying from one to nine months. Courses were available to practicing physicians throughout the year in thirty-five centers.

In only three instances was the work in the short intensive courses wholly didactic. In most cases it was indicated that all available facilities were advantageously used in the instruction. Clinical instruction and practical experience included laboratory and operative demonstrations, symposiums, assignment of patients, case presentation, clinical pathologic and roentgen ray conferences, movies and bedside teaching. As particular experience in special courses, facilities were utilized for dog surgery, laboratory experience, antepartum and postpartum clinics and home deliveries. In addition to medical schools and hospitals, laboratories, outpatient departments, clinics and local health units cooperated by placing their facilities at the disposal of the students.

The faculties of the medical schools offering continuation courses were called on for assistance in instruction in all but three courses. Many additional instructors were specialists in their fields, an equal number being chosen from within the state as from out of state.

REGISTRATION

All of these circuit courses had as their purpose the instruction of physicians practicing in or near the community in which the course was given. The practicing physician was invited to twenty-three of these courses; in eight others membership in the county medical society was a requirement. The number registered for any one course ranged from 37 in one state to 1,459 in another. The median number was 439 enrolled in extramural continuation study courses in any one state.

The M.D. degree was necessary for enrolment in all courses featuring clinical instruction, and in only a few were additional qualifications required. Medical students were admitted to two courses, and public health workers, hygienists and psychologists registered in four specialized courses. M.D.'s reported attending these continuation courses totaled 12,548. Small classes for intensive instruction and the individual use of clinical facilities were the rule. Fifty-four centers had registrations of less than 40; in fifteen the enrolment ranged from 40 to 75, in twelve from 75 to 200 and in thirteen over 200. In only six instances were more than 500 physicians registered, this enrolment usually indicating repeated short courses held in postgraduate schools or departments throughout the year. As an exception, the course in ophthalmology at George Washington University School of Medicine was given for over 500 physicians, and the course in aviation medicine for 170.

FINANCIAL SUPPORT

For twenty-four of the peripatetic continuation courses no charge to the physician was made. Only one fee was more than \$10, and in nine courses in which a registration fee was charged it was \$10 or less. Twenty-four state medical societies made substantial contributions to these programs. Federal funds were available through state agencies, and fifteen courses benefited. In the field instruction eight extension divisions of universities participated, and continued financial assistance was given in four instances by the Commonwealth Fund, the Rackham Fund and the Kellogg Foundation.

In continuation courses featuring clinical instruction of more than five days in one center the fees required ranged from a registration fee of \$2 to tuition of \$1,000. In twenty-three courses no fees were charged the individual; state departments of health used federal funds to defray the costs in nineteen of these. Funds secured from federal bureaus also assisted in financing seven courses for which a small registration fee was charged. Medical schools contributed most frequently, with state departments of health and state medical societies sharing expenses. Special contributions were made by the Bingham Associates Fund, the Commonwealth Fund of New York, the Rosenberg Foundation, the Rackham Fund, the Kellogg Foundation, the Mayo Foundation, the Trudeau Foundation and the Lillie Babbitt Hyde Foundation.

CLINICAL CONFERENCES, GRADUATE ASSEMBLIES
AND STUDY COURSES

In twenty-eight states and the District of Columbia graduate assemblies of less than five days and study courses were held during 1940-1941. These data are summarized in table 2, pages 722-725. Fifty-two reported assemblies or short lecture courses were held under the auspices of sixty-four agencies either independently or in collaboration. Fifteen state medical societies and thirteen medical schools sponsored conferences and assemblies. Six were planned by departments of welfare. In twelve instances postgraduate medical societies organized for the sole purpose of conducting assemblies were publicized as the sponsors. Several of these stemmed from county medical societies, and, in addition, committees of seven county medical societies directed such courses. Only four heart and tuberculosis associations reported this type of study, and three hospitals were responsible for conference courses. An especially appointed director of the clinics or chairman of the committee responsible for the assembly was reported for three fourths of the courses. In the remaining fourth in medical schools, hospitals and departments of health, the director was of the faculty or staff.

The majority of the large assemblies surveyed pertinent topics in general medicine and surgery, twenty-eight reporting this field covered in the lectures. Conferences devoted to more than one or two specialties were three in number. Scattered study courses sponsored by medical societies or agencies concentrating on certain fields included the varied subjects, as allergy, cardiology, electrocardiology, geriatrics, metabolism, industrial hygiene, obstetrics, office surgery, ophthalmology, otolaryngology, psychoneuroses, poliomyelitis, pneumonia typing, pediatrics, public health, tuberculosis and venereal disease. With one exception all

continuous conferences were of four days or less. Ten study and lecture courses were given intermittently over a month or more. The assemblies were usually held in centers large enough to accommodate the registrants and with facilities for clinical and practical work and for scientific exhibits. The programs were distributed rather evenly throughout the year, sixteen scheduled in the fall, ten during the winter and eighteen in the spring. A few others were given in the summer, and some in metropolitan areas were repeated throughout the year.

Of the fifty-two courses, eighteen were confined to didactic instruction. The remainder planned to utilize the facilities of hospitals, medical schools, outpatient departments and laboratories to conduct clinics, demonstrations, clinical pathologic conferences and symposiums. Faculty members of medical schools took an active part in forty-two of the courses. Instructors not from faculties of medicine were evenly divided between physicians from the state and physicians engaged from outside the state.

Practicing physicians were eligible for admission to all the graduate assemblies, and four courses sponsored by medical societies required membership in the county medical society. Medical students were invited to be guests at six of the courses. Registration fees ranged from \$1 to \$50 in twenty-five courses; in seventeen no registration fee was charged. The largest attendance recorded at any one assembly was 1,700; one class had but 4 physicians enrolled. The medical attendance during the past year was 209.

Thirty-six medical and clinical societies supported programs of this type; the departments of health through federal funds gave financial assistance to six. Four tuberculosis associations and thirteen medical schools supported, in part, as many courses.

OPPORTUNITIES FOR NEGRO PHYSICIANS

The Flint-Goodridge Hospital of Dillard University, New Orleans, has completed the first five years of the annual two week postgraduate course for Negro physicians. Approximately 20 per cent of these physicians of ten Southern states have attended one or more sessions. The faculty is composed chiefly of members of the medical school faculties of Tulane University of Louisiana and Louisiana State University, New Orleans, in addition to visiting lecturers.

The Meharry Medical College, Nashville, Tenn., during August and September 1940 gave a series of short courses in pediatrics for eighteen physicians sent to the college by the Division of Maternal and Child Health, the Department of Health of South Carolina. Each course was of two weeks' duration and registration for each was limited to five physicians. Round table discussions and bedside and clinic practice under close supervision were included.

The first postgraduate assembly for Negro physicians in South Carolina was held at State College, Orangeburg, over three days in January 1941. The National Tuberculosis Association, the U. S. Public Health Service and five South Carolina organizations sponsored the assembly. Lectures in obstetrics, pediatrics, tuberculosis and venereal diseases were given by five South Carolina and four out of state physicians.

The success of the first annual Postgraduate Institute for Negro Physicians held in Pittsburgh prompted repetition of the four day meeting in Philadelphia during

April 1941. Subjects included were tuberculosis, syphilis, child health and maternal welfare. The institutes were sponsored by the Medical Society of the State of Pennsylvania.

Short courses of from one to two weeks were given at Tuskegee Institute, Alabama, at the University of Georgia School of Medicine and at the Medical College of Virginia.

SUMMARY

1. Forty-four states and the District of Columbia provided a form of continuation study for physicians and, when clinical conferences were included, forty-five states and the District of Columbia offered graduate opportunities. From Delaware, New Hampshire and Wyoming no courses were reported.

2. There were twenty-eight states that offered continuation study for the practicing physician in or near their home community. There were twenty-eight distinct programs, which reached a total of three hundred and eight towns. State medical societies independently or with state boards of health sponsored the majority, while extension divisions of universities and state tuberculosis and public health associations cooperated in some states. Continuation study in centers where there are ample clinical facilities were offered in seventy-six centers located in thirty-three states and the District of Columbia. Ninety-nine agencies or combinations of agencies in forty states participated in the planning of the programs, although courses sponsored by ten state agencies were given outside the state. Medical schools offered more than half of the courses, including postgraduate schools or graduate departments of medical schools. Second in sponsoring programs were state health departments, while state medical societies collaborated with health departments or independently planned courses for the physicians of the state.

3. The approximate attendance at these circuit courses, centralized clinical courses and graduate assemblies totaled 43,621. The individual registration of these groups in the order named was 14,063, 12,548 and 17,010.

4. The study of general medical and surgical subjects or the various specialties or subspecialties in various combinations were offered. Clinical instruction and practical experience included laboratory and operative demonstrations, symposiums, assignment of patients, case presentation, clinical pathologic and roentgen ray conferences, movies and bedside teaching.

5. Out of state instructors participated as frequently as physicians of the state. Faculties of medical schools contributed 80 per cent of the instructors for the extramural courses and conducted most of the instruction in which clinical material was featured over five days or more.

6. Registration fees were charged infrequently for those courses offered in smaller communities, and in only one instance was a fee of more than \$10 charged. For graduate programs featuring clinical instruction at one center, fees ranged from \$2 to \$1,000.

SCIENTIFIC SOCIETIES

Organizations holding scientific sessions not primarily graduate assemblies, but of specific value to the practicing physician, numbered one hundred and seventy-eight. The annual scientific program of the American Medical Association was the climax of sessions in forty-seven states, the District of Columbia, Hawaii, the Philippines and Puerto Rico. National societies representing all of the specialties held seventy-seven meetings of from one to six days' duration. Twenty-five interstate agencies sponsored meetings, as did several special state and metropolitan organizations.

APPROVED EXAMINING BOARDS IN MEDICAL SPECIALTIES

At the annual session of the American Medical Association in 1933 the House of Delegates authorized the Council on Medical Education and Hospitals to formulate standards and officially approve such certifying boards in the specialties as would meet these requirements. Examining and certifying boards had already been established in ophthalmology, otolaryngology, obstetrics and gynecology and in dermatology and syphilology, but it was felt that there was need for a national and uniform standard governing all fields of medical practice in order that properly qualified physicians might readily be differentiated from the self-appointed specialists. The resolution of the House of Delegates urged that the machinery of the American Medical Association, including the publication of the American Medical Directory, be used in furthering the work of boards accredited under this plan.

Standards governing the approval of specialty boards were formulated by the Council and approved by the House of Delegates in 1934. These standards relating to the organization and operation of these boards contain also the minimum qualifications required for certification as a specialist. The latter include graduation from an approved medical school, an internship of not

less than one year in a hospital acceptable to the Council, and a period of specialized training in a selected field.

Approved Examining Boards in Medical Specialties

Key No A B	Name of Board	Year of Incorporation	Certificates Awarded* Total Issued to	
			March 1, 1940	July 1, 1941
1	American Board of Pediatrics	1923	1,370	1,710
2	American Board of Psychiatry and Neurol ogy	1934	852	1,140
3	American Board of Orthopaedic Surgery	1934	652	704
4	American Board of Dermatology and Surgery	1932	492	539
5 A	1934	1,404	1,691
6 A	1935	677	784
7	American Board of Obstetrics and Gynecology	1920	1,051	1,469

9 Amer	1936	766	855
10 Amer	1937	1,766	1,875
11	American Board of Otolaryngology	1924	2,977	3,265
12	American Board of Surgery	1917	1,274	1,701
13	American Board of Anesthesiology	1935	86	132
14	American Board of Plastic Surgery	1937	169	169
15	American Board of Neurological Surgery	1940	..	85
Totals			15,791	18,617

* Active diplomates.

** Certification in the subspecialties: Allergy 59; cardiovascular disease 56; gastroenterology 11; tuberculosis 9; total, 125.

Fifteen specialty boards, eleven of which have been organized since 1933, meet the standards of the Council and are now fully approved by the Council, representing the following specialties:

Anesthesiology	Pathology
Dermatology and Syphilology	Pediatrics
Internal Medicine	Plastic Surgery
Neurological Surgery	Psychiatry and Neurology
Obstetrics and Gynecology	Radiology
Ophthalmology	Surgery
Orthopaedic Surgery	Urology
Otolaryngology	

The American Board of Plastic Surgery has not as yet examined any candidates, although certificates have been issued to those in the founders' group. All other boards regularly hold examinations for certification. The dates of examinations of these boards are published in *THE JOURNAL* every other week. To conserve space in the biographic section of the American Medical Directory, a key number has been assigned to each board. Those certified by these boards, with the exception of plastic surgery and neurological surgery, are so identified in the sixteenth edition of the Directory. The American Board of Plastic Surgery had expressed the desire not to credit in this edition its diplomates, since all eligible had not had an opportunity to receive certification, while the American Board of Neurological Surgery was incorporated after publication of the Directory.

Final action was taken in regard to the recognition of proctologists by the American Board of Surgery on May 1 last. The American Board of Surgery will now recognize those qualified in the field of proctology, provided such applicants meet the same requirements as exacted of those wishing to qualify in general surgery and pass the same examination as is required of the board's regular applicants. In addition to this, those desiring to qualify in the field of proctologic surgery will be required to pass an additional clinical test to be given by a committee representing the proctologic field immediately following the examination in part II as given by this board. The Council on Medical Education and Hospitals approved this arrangement.

The American Board of Internal Medicine, under a somewhat similar arrangement, has certified specialists in allergy, cardiovascular disease, gastroenterology and tuberculosis.

The identifying numerical symbols of the boards, the year incorporated, the number of certificates awarded up to March 1, 1940 and July 1, 1941, respectively, appear in the accompanying tabulation. The number certified by some of the boards has been reduced by death. Recorded therefore are the active diplomates.

On July 1, 1941 there were 18,645 physicians certified by the fifteen boards in operation at that time. In 1940 on March 1, 15,594 had been certified, and 3,051 for the following sixteen months. In internal medicine 2,679 physicians have been certified and in surgery 1,703. These boards have been operating less than five years. The greatest number certified by any one board were 3,265 who received the certificate of the American Board of Otolaryngology since its organization in 1924. This is the second oldest board in existence.

Each of these boards has published a booklet containing a brief statement regarding its organization, personnel, purposes and qualifications for eligibility for certification. The data contained in these announcements are reproduced herewith.

AMERICAN BOARD OF ANESTHESIOLOGY, Inc.

RALPH M. WATERS, President, Madison, Wis.
HENRY S. RUTH, Vice President, Merion Station, Pa.
PAUL M. WOOD, Secretary-Treasurer, 745 Fifth Avenue, New York.
JOHN S. LUNDY, Rochester, Minn.
EMERY A. ROVENSTINE, New York.
HARRY BOYD STEWART, Tulsa, Okla.
RALPH M. TOVELL, Hartford, Conn.
PHILIP D. WOODBRIDGE, New Haven, Conn.
CHARLES F. MCCUSKEY, Glendale, Calif.

HISTORY

The plan for this organization was devised to conform with those of other examining boards in medical specialties, by a committee representing the American Society of Anesthetists, Inc., the American Society of Regional Anesthesia, Inc., and the Section on Surgery of the American Medical Association. These organizations adopted the tentative plans submitted, and the formation of the American Board of Anesthesiology, Inc., an affiliate of the American Board of Surgery, Inc., was completed on June 2, 1937. The Advisory Board for Medical Specialties, and the Council on Medical Education and Hospitals of the American Medical Association approved the affiliation in 1938.

In 1941 the Advisory Board for Medical Specialties approved the establishment of the American Board of Anesthesiology, Inc., as a separate major board, with the unanimous consent of the participating societies and the surgical boards which are members of the Advisory Board.

Diplomates of this Board will be designated "A.B. 13" in the Directory and Biographical Departments of the American Medical Association.

PURPOSES

1. To establish criteria of fitness to be designated a specialist in the practice of anesthesiology.
2. To improve educational facilities and practice in medical schools and hospitals, and furnish lists of these, together with lists of individual instructors who give adequate instruction and training in anesthesiology.
3. To arrange, control, and conduct examinations to determine the qualifications, and grant a certificate to those who voluntarily apply and meet the required standards. Such certification will serve to provide the public and the professions with the opportunity to select the best available service. (Conferring of degrees is a prerogative of the universities, and the Board of Anesthesiology makes no attempt to grant degrees, regulate or control the practice of anesthesiology in any way whatsoever, by license or restriction.)

VALUE OF CERTIFICATE

The organizations which participate in forming this board and sponsoring the activities as well as other societies or institutions, attach considerable importance to its certificate. The medical and lay public, as well as hospital directors, utilize the certification by this board in determining those who are well qualified as specialists in anesthesiology.

Although the Directory of the American Medical Association indicates those practicing in the various specialties the lists of holders of certification by specialty boards are available in the form of the Directory of Medical Specialists.

The American Board of Anesthesiology will cooperate with institutions and individuals in preparing plans for instruction in anesthesiology and in offering suggestions for the organization of new departments in the specialty.

QUALIFICATIONS FOR ELIGIBILITY TO CERTIFICATION

- A. General.—1. An applicant's moral and ethical standing in the profession must be satisfactory to the entire board. The board must be assured that the applicant is engaged in the practice of anesthesiology as a specialty and that he intends to continue to be so engaged.
2. Membership is required in the American Medical Association or membership in such other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association. Membership in other societies shall not be required.
3. Practice must be limited to anesthesiology.
4. In exceptional instances the board may, in its discretion, accept for examination candidates who have met all the preliminary requirements and have clearly demonstrated their identity as an anesthetist over a period of years but whose formal training does not comply with the full requirements to be exacted in the future.

B. *Professional Standing*.—1. An applicant must be a graduate of a grade A school in the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association, or a graduate of an approved foreign school.

2. Satisfactory evidence must be supplied of completion of an internship of not less than one year in a hospital approved by the same council, or its equivalent in the opinion of the board.

3. An applicant must establish in a manner satisfactory to the Board of Anesthesiology: that he is a physician duly licensed by law to practice medicine; that he is of high ethical and professional standing, and that he has received adequate special training in anesthesiology.

C. *Special Training and Practice*.—1. Before certification the candidate must have had an active experience limited to anesthesiology of not less than five (5) calendar years (including period of training).

2. The board recommends the inclusion of at least two years of carefully supervised instruction in the clinical phases of anesthesiology in hospital clinics, dispensaries, and diagnostic laboratories recognized by the Council on Medical Education and Hospitals of the American Medical Association as competent in the teaching and practice of anesthesiology. In addition, instruction in anatomy, physiology, pharmacology, biochemistry and other basic sciences which are necessary to the proper understanding of the problems involved in the specialty of anesthesiology is required.

(The board believes that for those entering the specialty after Jan. 1, 1944, the facilities for special training in anesthesiology will be available and such training will be sufficiently standardized that special training in anesthesiology may be interpreted to include after that date:

(a) A period of study, after the internship, of not less than three years in clinics, dispensaries, hospitals, and laboratories recognized by the Council on Medical Education and Hospitals of the American Medical Association as competent to provide a satisfactory training in the special field of anesthesiology.)

EXAMINATIONS

The qualifying examination will be divided into Part I, written, Part II, oral, and Part III, practical.

PART I

1. An applicant, to be eligible for Part I, must meet all requirements and his credentials must be approved by the board.

2. At the board's discretion a candidate may apply for certification and may take the written examination on basic science and clinical practice on the completion of two years of his courses of special training. Subsequently it shall be necessary for him to await the prescribed length of time to proceed with further examinations. Candidates who successfully pass Part I examinations (and satisfy the time requirement) proceed automatically to Part II examinations.

3. Part I may be given simultaneously in several centers, throughout the United States, which the board may determine suitable for the purpose.

PART II

1. In order to be eligible for Part II, a candidate must have successfully passed Part I in addition to having met the necessary requirements and having presented definite evidence of an adequate experience in anesthesiology satisfactory to the board.

2. It is probable that Part II examinations will be held near the time and at the place of the annual convention of the American Medical Association. Later, however, as the demand grows, it may be necessary to establish subsidiary centers where this part may be held.

PART III

1. It is believed that the practical examination in this field is slightly different from that in most specialties. The examiners will observe the work of the candidates in their own or similar operating room surroundings, their relations to other staff members, and investigate their professional standing.

CONDUCT OF EXAMINATION

Carefully conducted and thorough examinations will be required of candidates. The aim will be to avoid unduly exacting standards above present facilities for study and practice in anesthesiology, and on the other hand, to prevent laxity, which would nullify the main purpose of the certificate. Thus the type of the examination will depend on a careful review of the work done, years of practice, special courses of study, and professional standing of the applicant.

Written examinations will cover such topics as anatomy, biochemistry, physiology, pharmacology, pathology, physical diagnosis, therapeutics, clinical practice, and public health in relation to anesthesiology.

Oral examinations will cover topics in the above list especially as to their clinical application.

Practical demonstrations will be required of the management of the candidate's clinical practice in his local surroundings. This may include inspection of clinical records, records of departmental activities, library facilities, available apparatus, and demonstrations of application of anesthetic agents, methods and all techniques included in anesthesiology.

GRADES

A candidate must receive a passing average for each part, to be entitled to certification. No candidate shall pass a part who does not receive a grade of 60 per cent or more in each subject of such part. An average grade of 75 per cent shall be required for passing.

A candidate who fails in his examination in Part I will have his papers reviewed by the entire board and will be entitled to reexamination at yearly intervals for two consecutive years without further payment of fee. The board may, however, for sufficient reason, deny a candidate the privilege of reexamination.

Applicants who fail to exercise the examination privilege within three (3) years of the date of filing the application are required to file a new application and pay a new application fee.

The fee shall be \$75. Twenty-five dollars shall be paid on filing the application (of which sum \$15 will be returned if the candidate is not accepted for examination) and the remaining \$50 shall be paid before taking the examinations.

This board is a nonprofit organization, all fees to be used to extend the existing facilities for training in anesthesiology, after deducting necessary expenses for maintenance of the office, and the conducting of examinations. The board reserves the right to increase the fee when found necessary.

REVOCATION OF CERTIFICATE

All certificates issued by the board shall be subject to revocation by the board at any time, in case it shall determine in its sole judgment that a candidate who has received a certificate either was not properly qualified to receive it or has become disqualified since its receipt.

ADDITIONAL INFORMATION

Every candidate applying for certification must personally appear before the board before being certified.

Application blanks must be made on special blanks which may be procured from the Secretary of the American Board of Anesthesiology. They must be completely and accurately filled out, accompanied by the other required credentials, and filed with the secretary of the board at least ninety days prior to the date of examination.

The Council cannot make any eligibility rulings. These are made only by the Committee on Preliminary Examinations and the Committee on Requirements and Credentials after reviewing the candidate's formal application. Applications cannot be considered for classification and action by these committees unless accompanied by an application fee of \$25.00, \$10.00 of which is not returnable.

Application blanks contain the following statement:

"I hereby make application to the American Board of Anesthesiology, Inc., for the issuance to me of a Certificate of Qualification as a Specialist in Anesthesiology and for examination relative thereto, all in accordance with and subject to its rules and regulations, and enclose fee of seventy-five dollars (\$75.00).¹ I agree to disqualification from examination or from the issuance of a Certificate of Qualification or to surrender of such certificate as directed by the board in the event that any of the statements hereinafter made by me are false or in the event that any of the rules governing such examinations are violated by me or in the event that I did not comply with or shall violate any of the provisions of the Certificate of Incorporation or Constitution and By-Laws² of the American Board of Anesthesiology, Inc., or both, as then constituted. I agree to hold the American Board of Anesthesiology, Inc., its members, examiners, officers and agents free from any damage or complaint by reason of any action they, or any of them, may take in connection with this application, such examinations, the grade or grades given with respect to any examination, or the failure of said board or corporation to issue to me such Certificate of Qualification."

Proper forms for making application and other information will be furnished by the secretary-treasurer.

1. This may be paid as follows: \$25 with application (\$10 registration fee not returnable) and \$50 before examination.

2. Ignorance of the provisions of the Certificate of Incorporation and of the Constitution and By-Laws is not considered by the board to be a valid excuse for violations.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY

HOWARD FOX, President, New York.
FREDERICK D. WEIDMAN, Vice President, Philadelphia.
C. GUY LANE, Secretary-Treasurer, 416 Marlboro Street, Boston.
CHARLES C. DENNIE, Kansas City, Mo.
JOSEPH GARDNER HOPKINS, New York.
HENRY E. MICHELSON, Minneapolis.
PAUL A. O'LEARY, Rochester, Minn.
FRANCIS E. SENEAR, Chicago.
JESSE BEDFORD SHELMIER, Dallas, Texas.

ORGANIZATION

At the 1931 meeting of the American Dermatological Association, a committee was appointed to determine the advisability of forming an American board for the certification of competent practitioners in this specialty similar to boards created by the ophthalmologists, the otolaryngologists and by the obstetricians and gynecologists. A similar committee was appointed by the Section on Dermatology and Syphilology of the American Medical Association at its meeting in the same year. A favorable report was rendered by each committee at the 1932 meeting of each of the above organizations.

The American Dermatological Association voted to accept the report of this committee, and the president appointed the following four members to represent the association on the newly formed American Board of Dermatology and Syphilology:

Dr. Jay F. Schamberg, Philadelphia.
Dr. Howard Fox, New York.
Dr. Harold N. Cole, Cleveland.
Dr. Arthur W. Stillians, Chicago.

The Section on Dermatology and Syphilology of the American Medical Association also accepted the report of its committee and the chairman appointed the following members to serve as its representatives:

Dr. Howard Morrow, San Francisco.
Dr. William H. Mook, St. Louis.
Dr. George M. MacKee, New York.
Dr. C. Guy Lane, Boston.

The first meeting of the board was held in New Orleans on May 11, 1932, at which time officers were elected. At another meeting held on Nov. 11, 1932, in Philadelphia the organization was completed and resolutions were adopted concerning the proper procedure to be followed by the board. On Nov. 29, 1932, the board was incorporated under the laws of the state of Delaware.

In 1937 the American Academy of Dermatology and Syphilology was formed, and in November 1939 a plan was finally approved whereby the board would be composed of three representatives from each national dermatologic society, viz., the American Dermatological Association, the Section on Dermatology and Syphilology of the American Medical Association, and the American Academy of Dermatology and Syphilology.

PURPOSES

The board has been established primarily to determine the competence of physicians who specialize in dermatology and syphilology. It will therefore establish minimum standards of education and training, examine applicants and certify properly qualified specialists in this field, prepare lists of those qualified and arrange for the publication of such lists. Because of its interest also in the fulfillment of these standards, it will attempt to stimulate the development of adequate training facilities, investigate institutions and individuals planning to train specialists, and lend its aid to the approval of those institutions and individuals offering adequate training in the specialty. The board, in addition, will always be glad to advise physicians desiring to enter this special field of medicine.

REQUIREMENTS FOR CERTIFICATION

I. General Requirements

1. High ethical and professional standing.
2. Graduation from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association.
3. Satisfactory completion of an internship of not less than one year in a hospital approved by the same Council.
4. A license to practice medicine.
5. Membership in the American Medical Association or membership in a similar society recognized as having the same purpose as the American Medical Association.
6. Citizenship in the United States or citizenship—meaning native citizens—in Canada and Cuba.

II. Special Requirements

Applicants for certification by the board are classed in two groups as follows:

Group A consists of physicians who have limited their practice mainly to dermatology and syphilology for ten or more years, including a period of training satisfactory to the board. This group will, in all probability, be abolished in 1949.

Group B consists of physicians who have practiced dermatology and syphilology at least five years, including their period of training. For such physicians who will be examined up to Jan. 1, 1945, the board will require two years of full-time planned training in clinical dermatology including adequate instruction in the following subjects as related to the skin: histopathology, mycology, allergy and physics as related to physical therapy.

III. Future Special Requirements

For candidates beginning their training after Jan. 1, 1940, who will appear for examination subsequent to Jan. 1, 1945, additional requirements are effective in accordance with the program recommended to the various specialty boards by the Advisory Board for Medical Specialties. These minimum requirements of special training for admission to examination are as follows:

1. A period of study, after the internship, of not less than three years in clinics, dispensaries, hospitals or laboratories recognized by the Council on Medical Education and Hospitals of the American Medical Association and approved by the American Board of Dermatology and Syphilology as competent to provide a satisfactory training in dermatology and syphilology. This period of specialized training shall include:

(a) Graduate training in the basic medical sciences which are necessary to the proper understanding and treatment involved in this specialty.

Instruction in the following fundamental subjects as related to the skin is deemed advisable by the board: embryology, histology, chemistry, physiology, bacteriology, mycology, parasitology, pathology, immunology, serology, pharmacology and materia medica, and physics of physical therapy.

(b) An active experience of not less than eighteen months in hospitals, clinics, dispensaries or diagnostic laboratories recognized by the same Council and approved by the American Board of Dermatology and Syphilology as competent to provide an adequate preparation.

(c) Examinations, written and oral, in the clinical, laboratory and public health aspects of dermatology and syphilology.

2. An additional period of not less than two years of study and/or practice.

Therefore, for certification by this board, candidates beginning their training after Jan. 1, 1940 must plan for a three years course of systematic training.

APPLICATION AND FEE

The board desires to appraise the candidate's educational opportunities (premedical, medical and dermatologic), the character of the men under whom he has worked, his hospital and teaching positions, original investigations, contributions to dermatologic literature, membership in medical societies and local and general reputation.

For this purpose, application must be made on a special blank, which may be obtained from the secretary. No application will be considered unless made on the regular application blank. Applications should be filed early in order to obtain full advantage of the sets of histopathological slides which are available through the Army Medical Museum in Washington. The completed application should be sent, at least two months before the date of examination, to the secretary of the board, together with the required reprints, photographs and the fee of \$35. This fee will not be returned, and no application will be considered until the fee is received. This fee has been carefully computed and is used entirely for administrative purposes. Members of the board do not receive any compensation except for actual expenses connected with holding the examinations.

Make checks payable to American Board of Dermatology and Syphilology, Inc.

EXAMINATIONS

Applicants classified in group B will be required to pass a written examination. This written examination on clinical and laboratory subjects including cutaneous pathology will be held simultaneously at stated intervals in different parts of the country, approximately two months before the oral examination.

Applicants classified in both groups A and B will be required to pass an oral, clinical and laboratory examination. This examination will be conducted in a clinic or hospital ward where individual cases will be discussed with each candidate as

well as various subjects related to the skin such as histopathology, mycology, allergy and physics of physical therapy. The board reserves the right to add to this list other subjects within the field of dermatology and syphilology.

Examinations are designed to test the candidate's fitness to practice dermatology and syphilology as a specialty. The board will try especially to ascertain the breadth of his clinical experience, his knowledge of recent literature of dermatology and syphilology and his general qualifications as a specialist in this branch of medicine.

Whenever an applicant fails to pass the examination, the board, if requested, will make suggestions as to suitable courses of instruction for the purpose of overcoming deficiencies in the applicant's knowledge of this specialty.

Except in special circumstances, applicants shall take the examination within the year following the filing of application and the deposit of the fee.

The oral examination will be held near the time and place of the annual meeting of the American Academy of Dermatology and Syphilology. This examination will be held only at the time of regular meetings of the boards.

REEXAMINATIONS

If the candidate fails or is "conditioned" in an examination he will be admitted to a second examination after one year, but within three years, and must give sixty days' notice of his intention to appear for reexamination. If a candidate who has failed or has been conditioned does not appear for reexamination before the expiration of three years, he will be required to make a new application and pay an additional fee of \$35 before reexamination.

A candidate having failed twice must file a new application and pay an additional fee of \$35.

CERTIFICATES

A certificate will be issued to each candidate who meets the requirements of the board, to the effect that the holder of the certificate has had adequate training in dermatology and syphilology and has successfully fulfilled the requirements of the board.

It is expected that medical schools, hospitals and physicians, as well as the lay public, will utilize the certificate from this board as a proof of adequate preparation in the field of dermatology and syphilology, and of fitness of candidates for positions under their control. For this purpose lists of those holding certificates from the board will be available for inspection and will be published from time to time in the Directory of Medical Specialists. Diplomates will be identified in the Directory of the American Medical Association.

A certificate granted by this board does not of itself confer or purport to confer, any degree, or legal qualifications, privileges, or license to practice dermatology or syphilology. The board does not intend to limit or interfere with the professional activity of any duly licensed physician. Its aim is to improve the standards of practice of dermatology and syphilology by encouraging improvement in the opportunities for and quality of training for specialists in this field of medicine, and to certify, as specialists those who voluntarily comply with the requirements of the board.

Upon the board rests the responsibility of determining the standards of knowledge to be acquired, while upon the candidate will always rest the responsibility of acquiring the knowledge to fulfill these standards.

Certificates will be issued only to physicians in the United States and its possessions, in Canada and in Cuba.

REVOCATION OF CERTIFICATES

The certificates issued by the board are issued subject to the provisions of the certificate of incorporation and of the by-laws, and each certificate is subject to revocation in the event that: (a) the issuance of such certificate or its receipt by the physician so certified shall have been contrary to any of the provisions of the certificate of incorporation or by-laws; or (b) the physician so certified shall not have been eligible to receive such certificate, irrespective of whether or not the facts constituting him so ineligible were known to or could have been ascertained by the directors of the board at the time of the issuance of such certificate; or (c) the physician so certified shall have made any misstatement of fact in his application for such certificate or in any other statement or representation to the board or its representatives; or (d) the physician so certified shall have been convicted by a court of competent jurisdiction of a felony or of any misdemeanor involving, in the opinion of the board of directors, moral turpitude in connection with his practice of medicine; or (e) the physician so certified shall have had

his license to practice medicine revoked or shall have been disciplined or censured as a physician by any court or other body having proper jurisdiction and authority.

PUBLICATIONS OF THE BOARD

1. Booklet of Information.
 2. Opportunities for Graduate and Postgraduate Students in Dermatology and Syphilology, containing a list of places where instruction may be obtained, and details about these places. (In preparation.)
 3. The complete register of diplomates is published in the Directory of Medical Specialists, which can be obtained from the Columbia University Press, New York City. \$5.00.
 4. Syllabus of graduate training.
 - (a) To inform the student physician, intending to specialize, of the field to be covered in his preparation and the methods by which his preparation can be accomplished.
 - (b) To aid the medical schools and the dermatologic department of medical schools and hospitals by outlining the scope of teaching required for specification in dermatology and syphilology.
- Further information may be obtained from the secretary-treasurer.

INSTRUCTIONS TO APPLICANTS

Fill out application blank in detail.
Enclose fee of \$35. (Make checks payable to the American Board of Dermatology and Syphilology, Inc.)
Include photographs as directed on application blank.
Enclose reprint of each published paper, if possible.
Send completed applications and above items to the secretary.
Please indicate under No. 13 on the application blank as complete data as possible about your training in dermatology and syphilis. Indicate the month and year, if possible, or at least the number of months of the various parts of your training and also whether full time or part time. If part time indicate whether one-half day, six days a week or three days a week, etc. If dispensary service is considered as part of your training, please indicate details here as well as under No. 14.
In No. 16 indicate clearly when you limited your practice to dermatology and syphilis.
If your training and your practice overlap, please explain under No. 19.

ADDENDA

At a meeting of the board held in New Orleans early in 1941 it was decided:

1. If a candidate is called into active military or naval service he will receive full credit for dermatological training already finished at that time.
2. So far as counting as training in dermatology and syphilology any military or naval medical service, each case must of necessity be decided upon the evidence submitted in the case of each particular candidate.
3. The board accept not more than one year of military medical service as part of the required two years' experience in dermatology and syphilology to be eligible for examination.
4. A candidate who is called into military or naval service after completion of three years of training may take the complete examination of the board, and that if this examination is satisfactory a certificate will be issued after satisfactory completion of two years of further approved experience in dermatology and syphilology.
5. A candidate for a certificate may take the written examination at the next regular examination of the board after he has completed three full years of training.

AMERICAN BOARD OF INTERNAL MEDICINE, Inc.

ERNEST E. IRONS, Chairman, Chicago.
REGINALD FITZ, Vice Chairman, Boston.
WILLIAM S. MIDDLETON, Secretary-Treasurer, 1301 University Avenue, Madison, Wis.
DAVID P. BARR, St. Louis.
WILLIAM J. KERR, San Francisco.
WILLIAM S. McCANN, Rochester, N. Y.
JONATHAN F. MEAKINS, Montreal, Quebec.
JOHN H. MUSSER, New Orleans.
GEORGE GILL RICHARDS, Salt Lake City.

"... the membership of the board shall be maintained at the ratio of five members from the American College of Physicians and four members from the Section on the Practice of Medicine of the American Medical Association and that at least three of the members of the board from the American

College of Physicians and two members of the board from the Section on the Practice of Medicine of the American Medical Association shall be of professorial rank in approved medical schools of the United States or Canada."

"Sec. 5, Art. 5, Articles of Incorporation."

HISTORY AND AUTHORITY FOR ORGANIZATION

The American College of Physicians, through its Board of Regents at the annual session in Philadelphia on April 30, 1935, adopted a resolution for the establishment, with the Section on the Practice of Medicine of the American Medical Association, of an "American Board for the Certification of Internists." This board to consist of nine members; six to be appointed by the American College of Physicians, and three by the Section on the Practice of Medicine of the American Medical Association.

At the annual meeting of the American Medical Association at Atlantic City, N. J., June 10-14, 1935, the Section on the Practice of Medicine adopted the following resolution: "Resolved, that a committee of three, including a chairman, be appointed by the chairman of the Section on the Practice of Medicine, to discuss with a committee from the American College of Physicians, ways and means by which an examining board, comparable to such boards already existing in certain specialties, may be set up for the purpose of certification of specialists in internal medicine.

President James Alexander Miller of the American College of Physicians appointed the following as representatives of the College on the joint committee: David P. Barr, St. Louis; Jonathan C. Meakins, Montreal; William S. Middleton, Madison; John H. Musser, New Orleans; O. H. Perry Pepper, Philadelphia; G. Gill Richards, Salt Lake City. William J. Kerr, Chairman of the Section on the Practice of Medicine of the American Medical Association, appointed Walter L. Bierring, Des Moines; Reginald Fitz, Boston, and Ernest E. Irons, Chicago, as representatives of that section. Walter L. Bierring was named as chairman of the joint committee.

The joint committee of nine members held its first meeting in Philadelphia Dec. 14, 1935. At this meeting a resolution was adopted to submit an application in due form to the Advisory Board for Medical Specialties requesting authority to organize the American Board of Internal Medicine and for admission to membership in the said advisory board. In the preliminary draft of the constitution and by-laws, the ratio of the representation on the board was changed to five members from the American College of Physicians and four members from the Section on the Practice of Medicine of the American Medical Association.

On Feb. 16, 1936 a subcommittee consisting of Walter L. Bierring, Reginald Fitz, Ernest E. Irons, Jonathan C. Meakins and William S. Middleton held a meeting in the Palmer House, Chicago, to formulate and complete the details of the application to be presented to the executive committee of the Advisory Board for Medical Specialties, which body approved the organization of the American Board of Internal Medicine and directed that articles of incorporation be completed and filed.

In keeping with the ratio of membership to be maintained on the American Board of Internal Medicine, James Alexander Miller, President, officially designated David P. Barr, Jonathan C. Meakins, William S. Middleton, O. H. Perry Pepper and G. Gill Richards as representatives from the American College of Physicians, and William J. Kerr, Chairman, designated Walter L. Bierring, Reginald Fitz, Ernest E. Irons and John H. Musser to represent the Section on the Practice of Medicine of the American Medical Association.

The articles of incorporation were filed for record with the county recorder of Polk County at Des Moines, Polk County, Iowa, Feb. 28, 1936.

At the annual session of the American College of Physicians, Detroit, March 1-6, 1936, the Board of Regents officially approved the American Board of Internal Medicine. On May 10, 1936 the Advisory Board for Medical Specialties, meeting in Kansas City, gave its final approval to the American Board of Internal Medicine, granting at the same time admission to membership in the Advisory Board for Medical Specialties.

The Council on Medical Education and Hospitals of the American Medical Association approved the board at its meeting May 12, 1936. The Section on the Practice of Medicine of the American Medical Association gave its final approval May 13, 1936. The first meeting of the board was held at the Palmer House, Chicago, June 14-15, 1936.

Subspecialty certification was authorized by the Advisory Board for Medical Specialties and the Council on Medical Education and Hospitals of the American Medical Association, Feb. 16, 1941. The mechanism for instrumenting this program has been perfected through the cooperation of advisory committees in allergy, cardiovascular disease, gastroenterology and tuberculosis.

PURPOSE

1. To improve the standards of practice and the quality of service in the field of internal medicine.
2. To determine the eligibility of candidates who request admission to examination in accordance with regulations published herein.
3. To conduct examinations of eligible candidates who seek qualification by this board.
4. To issue certificates of qualification to all those meeting the requirements of the board.
5. To aid in improving the educational opportunities for the training of internists.
6. To administer the regulations which pertain to certification in the medical subspecialties referred to herein.

VALUE OF CERTIFICATION

1. Evidence of special training in the broader aspects of the field of internal medicine and recognition of qualifications for the practice of internal medicine as a specialty.
2. A requirement for admission to Fellowship in the American College of Physicians.

QUALIFICATIONS OF CANDIDATES

Each applicant for admission to the examination shall be required to present evidence that he has met the following standards:

1. GENERAL.

- A. Satisfactory moral and ethical standing in the profession.
- B. Membership in the American Medical Association or, by courtesy, membership in such Canadian or other medical society or societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association. Except as here provided, membership in other societies shall not be required.

2. PROFESSIONAL.

- A. Graduation from a medical school of the United States or Canada approved by the Council on Medical Education and Hospitals of the American Medical Association.
- B. Completion of an internship of not less than one year in a hospital approved by the same council.
- C. In the case of an applicant whose training has been received outside of the United States and Canada, his credentials must be satisfactory to the aforementioned council and the Advisory Board for Medical Specialties.

3. SPECIAL TRAINING.

A minimum of five years must elapse after completion of a year of internship in a hospital approved for intern training before the candidate is eligible for admission to an examination.

A. Three years of this period must be devoted to special training in internal medicine. This requirement should include a period of at least several months of graduate work under proper supervision in anatomy, physiology, biochemistry, pathology, bacteriology or pharmacology, particularly as related to the practice of internal medicine. This work may be carried on in any domestic or foreign medical school or laboratory recognized by the Council on Medical Education and Hospitals of the American Medical Association as offering appropriate facilities for this type of postgraduate training; or it may include a period of at least two years of graduate work under proper supervision in internal medicine or in its restricted and specialized branches in any domestic or foreign hospital, clinic or dispensary, or under the immediate preceptorship of an internist recognized by the board as offering appropriate facilities for this type of postgraduate experience.

B. A period of not less than two years of special practice in the field of internal medicine or in its more restricted and specialized branches.

MEMORANDUM FOR THE GUIDANCE OF CANDIDATES

The American Board of Internal Medicine does not propose to establish fixed rules for the preliminary training of candidates for certification in this field. Broad general principles for training, however, may be outlined, although such suggestions as are made must of necessity be subject to constant changes reflecting the dynamic nature of the specialty.

1. A sound knowledge of physiology, biochemistry, pharmacology, anatomy, bacteriology and pathology in so far as they apply to disease is essential for continued progress of the individual who practices internal medicine. Such knowledge may be obtained in a number of ways:

A. By properly arranged and supervised graduate courses;

B. By the opportunities for study afforded by the appointment to a junior position in a department of physiology, biochemistry, pathology, etc. (see above) with attendance upon advanced lectures in the other subjects;

C. By advanced study in these subjects while an intern or resident medical officer, and by the application of the principles involved to patients under one's control;

D. By the detailed study, under supervision, of a problem or topic in medicine in which the student brings the basic facts of physiology, pathology, etc., into direct relation with the concrete clinical problem. The analysis of a problem with detailed knowledge of its fundamental pathologic or physiologic background does much to stimulate thoroughness, clear thinking and progress.

2. A portion of the written examination is designed to test the candidate's knowledge in these "preclinical" subjects and especially in their application to disease rather than their purely laboratory aspects.

3. The mere factual knowledge of medicine and its basic sciences is not sufficient. The candidate must have had training in their use in furthering his understanding in clinical medicine. This implies practical experience under the guidance of older men who bring to their clinical problems ripe knowledge and critical judgment. Preparation to meet this requirement adequately may be even more difficult to obtain than the so-called scientific training. It may, however, be acquired in the following ways:

A. By work in a well organized hospital outdoor clinic conducted by competent physicians;

B. By a prolonged period of resident hospital appointments likewise directed by skilled physicians;

C. By a period of training in intimate association with a well trained and critical physician who takes the trouble to teach and guide his assistant rather than to expect him only to carry out the minor drudgery of a busy practice.

4. The board does not consider it to be the best interests of internal medicine in this country that rigid rules be formulated as to where or how the training outlined above is to be obtained. Medical teaching and knowledge are international. The opportunities of all prospective candidates are not the same. Some may have the opportunity of widening their knowledge by a period of study abroad. Others, at the other extreme, may be restricted to a comparatively narrow geographic area and their more detailed training must be obtained in short periods of good study scattered over a longer time. Although it is required that at least five years must elapse between the termination of the first intern year and the date when the candidate is eligible to take the examination, a longer period is advisable. The board wishes to emphasize that time and training are but a means to the end of acquiring a broadness and depth of knowledge of internal medicine which the candidate must demonstrate to the board in order to justify it in certifying that he is competent to practice internal medicine as a specialty. The responsibility of acquiring the knowledge as best he may rests with the candidate, while the responsibility of maintaining the standard of knowledge required for certification devolves on the board.

5. Applicants who graduated before the foundation of the American Board of Internal Medicine in 1936 will not be held to the strict interpretation of the published requirements in formal graduate training. Under such circumstances the board will accept the results of the examination as evidence of the qualifications for certification.

6. The board will recognize one year of basic science training which leads to a *higher degree* in the basic sciences, as one year of formal graduate training, whether taken previous to or subsequent to the first year of internship.

7. The board will recognize a second year of internship which is confined strictly to internal medicine as one year of the graduate training period.

8. The board will recognize one year of training in pediatrics, neurology or any medical subspecialty as one year of the graduate training period of three years as published herein.

9. In all instances the board will require a minimum of two years training in internal medicine.

10. In the current emergency the board will allow one year of military service in the United States Army, Navy, or Marine Corps to be applied toward the satisfaction of one year of graduate training, or one year of the practice of the specialty of internal medicine. This ruling admits of a substitution of military or naval service for only one year of the three years of graduate training, or one year of the two years of the practice of internal medicine as outlined in the published qualifications for admission to the examination of this board.

METHOD OF EXAMINATION

The examination required of candidates for certification as specialists in internal medicine will comprise Part I (written), and Part II (practical or clinical).

Part I. The written examination is to be held simultaneously in different sections of the United States and Canada on the third Monday of February and October of each year. This examination will be divided into a morning and an afternoon session of three hours each, and the two sessions A and B will include the following:

A. Question in applied physiology, anatomy, physiological chemistry, pathology, bacteriology and pharmacology as related to internal medicine as well as the cultural aspects of medicine.

B. Questions in general internal medicine.

The location of the written examination is determined by the number of candidates from any given area. In all instances, however, the board will make every effort to meet the convenience of all concerned with a minimum of expense and time.

All candidates must successfully pass the written examination before being admitted to the oral examination.

Part II. Candidates successful in the written tests will be eligible for the practical or clinical examination, which will be conducted by the members of the board near the time and place of the annual meeting of the American College of Physicians and of the American Medical Association and at such other times and places as the board may designate. This examination is conducted at the bedside, and each candidate will be assigned one or more patients in the hospital.

REEXAMINATIONS

1. Any candidate unsuccessful in the written examination may upon request repeat the examination after a period of two years. No additional fee is required for this examination. Any candidate unsuccessful in a second written examination may upon request repeat the examination after a further period of two years. A fee of \$10 is required for admission to a third written examination.

2. Any candidates unsuccessful in the oral examination may upon request repeat the examination after a period of one year. The period of one year is construed as the interval between annual meetings of the American College of Physicians or annual meetings of the American Medical Association. No additional fee is required for this examination. Candidates unsuccessful in the second oral examination may, upon request, repeat the examination after a period of two more years. A fee of \$10 is required for admission to the third oral examination.

APPLICATION

Candidates for examination shall make their application on a prescribed form which may be obtained from the office of the secretary-treasurer.

The application shall contain a record of the candidate's premedical and medical training as well as of internships, graduate study, hospital or dispensary staff appointments, teaching positions, membership in medical societies, medical papers published and the names of two well known internists to whom the board may refer for professional and character reference.

The application shall also be accompanied by one recent signed photograph mounted on the application, and the registration and examination fee of \$40, which fee will cover both the written and practical examinations. An additional fee of \$10 will be required when the certificate is issued.

CERTIFICATES

The certificate issued by the American Board of Internal Medicine shall be in such form as to comply with the articles of incorporation and the by-laws and shall be signed by the officers and members of the board, and shall bear the official seal of the board.

Certificates of the board will be issued to candidates who have satisfactorily completed the written and practical examinations, and been found qualified by the board to practice the specialty of internal medicine.

Subspecialty certification will be designated on the certificate.

CERTIFICATION IN MEDICAL SUBSPECIALTIES

In association with the advisory committees in allergy, cardiovascular disease, gastroenterology and tuberculosis, the American Board of Internal Medicine will:

1. Certify without examination candidates who have been certified by this board and who have been recommended by the advisory committee of the sub-specialty concerned for certification without examination.

2. Admit to further examination and certify if qualified, candidates who have been certified by this board and who have been recommended by the advisory committee of the sub-specialty concerned as eligible for admission to the examination.

3. Examinations for certification in the sub-specialties indicated will be conducted by guest examiners, nominated by the advisory committee concerned and selected by the American Board of Internal Medicine, at the time and place of the regular board examinations. A fee of \$10 is required to meet the expense of this examination.

4. Candidates who have not been certified by the American Board of Internal Medicine are ineligible for admission to examination in any sub-specialty.

The American Board of Internal Medicine and members of advisory committees in the sub-specialties referred to herein, recognize the value of a broad general training in internal medicine before attempting to qualify in a sub-specialty of medicine. It is, therefore, agreed that all candidates shall first be certified by the American Board of Internal Medicine as a prerequisite for certification in a sub-specialty.

REVOCATION OF CERTIFICATES

The American Board of Internal Medicine shall have the sole power, jurisdiction and right to determine and decide whether or not the evidence or information placed before it is sufficient to constitute grounds for revocation of any certificate issued by this board, and the decision of the board in the premises shall be final.

All official correspondence should be addressed to the secretary-treasurer.

ORGANIZATION

In 1930 the American Association of Obstetricians, Gynecologists, and Abdominal Surgeons, the American Gynecological Society, and the Section on Obstetrics and Gynecology of the American Medical Association, each elected three Fellows to constitute the American Board of Obstetrics and Gynecology.

Dr. Walter T. Dannreuther of New York, Dr. Paul Titus of Pittsburgh and Dr. Grandison D. Royston of St. Louis were appointed to represent the American Association of Obstetricians, Gynecologists, and Abdominal Surgeons; Dr. Jennings C. Litzenberg of Minneapolis, Dr. Joseph L. Baer of Chicago, and Dr. E. A. Schumann of Philadelphia were appointed to represent the American Gynecological Society; Dr. Fred L. Adair of Chicago, Dr. R. D. Mussey of Rochester, Minn., and Dr. E. D. Plass of Iowa City were appointed to represent the Section on Obstetrics and Gynecology of the American Medical Association. Since formation of the board several of the original members have resigned and others have been duly appointed to fill their places.

The board was incorporated and organized and held its first meeting in September 1930. At that time the By-Laws were adopted and provision was made by resolutions for its proper functioning.

This board had been in the process of organization since 1927 and put into action a determined effort on the part of these three national organizations to improve the standards of practice of obstetrics and gynecology.

Experienced practitioners of the specialty have been required to undergo a practical clinical examination, whereas a younger group has had both a written and clinical examination and was

required also to submit reports of a group of cases in order to qualify for certification.

After the 1942 examinations, no such distinction will be made, and all applicants will be obliged to fulfill all of the requirements, including the written examination in obstetrics and gynecology and submission of case records, as well as the general oral-clinical and pathological examination in obstetrics and gynecology.

PURPOSES

First. To elevate the standards and advance the cause of obstetrics and gynecology.

Second. To determine the competence of practitioners professing to be specialists in obstetrics and gynecology.

Third. To arrange, control and conduct examinations to test the qualifications of voluntary candidates appearing before the board for certification as specialists in obstetrics and gynecology.

Fourth. To grant and issue certificates of qualification as specialists in the field of obstetrics and gynecology to candidates successful in demonstrating their proficiency.

Fifth. To serve the public, hospitals and the medical schools by preparing lists of specialists certified by the board.

These activities proceed from the certificate of incorporation in which it is stated that "the nature of the business and the objects or purposes proposed to be transacted, promoted and carried on by it" are as follows:

"To encourage the study, improve the practice, and advance the cause of obstetrics and gynecology, subjects which should be inseparably interwoven; and to grant and to issue to physicians duly licensed by law, certificates or other equivalent recognition of special knowledge in obstetrics and gynecology."

NO DEGREES OR LEGAL RESTRICTIONS

Each certificate granted or issued does not of itself confer or purport to confer upon any person any degree or legal qualifications, privileges or license to practice obstetrics or gynecology, nor does the board intend in any way to interfere with or limit the professional activities of any duly licensed physician. Its chief aim is to standardize qualification for specialists in obstetrics and gynecology, and to certify as specialists those who voluntarily appear before the board for such recognition and certification, according to its regulations and requirements.

VALUE OF CERTIFICATE

The national obstetrical and gynecological organizations, which have participated in the formation of the board and are sponsoring its activities, as well as other societies, attach considerable importance to its certificate. Both the medical and the lay public, including hospital directors, have come to utilize the certificate from this board freely as a means of determining who are well grounded as specialists in obstetrics and gynecology.

Lists of those holding certificates from this board who are limiting their practice to obstetrics and gynecology are published in the *Directory of Medical Specialists*; similar lists are published by the *American Journal of Obstetrics and Gynecology*, and also appear in the *American Medical Directory*. This latter indicates diplomates of this and other boards by means of numerical symbols appearing in the biographic records.

A joint directory of specialists certified by the fifteen major special boards was published in 1940 by the Advisory Board for Medical Specialties, and a new edition appears again in 1942. This board holds active membership in the Advisory Board for Medical Specialties.

This board, in cooperation with the Council on Medical Education and Hospitals of the American Medical Association, is conducting a survey of institutions providing acceptable residencies and internships in obstetrics and gynecology.

PREREQUISITES TO ELIGIBILITY

Each applicant before he shall become eligible to receive such certificate or other evidence of recognition:

1. Must have had conferred upon him a degree in medicine by an institution of learning approved by the Advisory Board for Medical Specialties and the Council on Medical Education and Hospitals of the American Medical Association.

2. Must establish in a manner satisfactory to the board of directors that he is a physician duly licensed to practice medicine.

a. That he is of high ethical and professional standing.

b. That he has received adequate training in obstetrics and gynecology as a specialty.

Each candidate should have certain fundamental knowledge of the basic essentials of anatomy, pathology, bacteriology, physiology, pharmacology, and therapeutics as related to the

practice of obstetrics and gynecology. Clinical training should consist, subsequent to graduation, of at least one year's general rotating internship, and thereafter a special residency in obstetrics and gynecology for a period of at least three (3) years, not necessarily consecutive. The board accepts the fifth or "intern" medical school year required at some schools in lieu of the usual fifth or intern "clinical training" year following graduation. As a substitute for special training, service with a qualified obstetrician-gynecologist preceptor, preferably one who has been certified by the board, may be acceptable. The exact time basis for this has not been specified, and each case must be reviewed and decided individually by the credentials committee after the application is submitted in the regular manner. The time allowance for this type of training will vary with the amount of work done with the preceptor. Opportunity for personal responsibility during this period of training is highly desirable. At least a fundamental knowledge of both obstetrics and gynecology is essential regardless of whether a candidate's practice is limited to one or the other branch. As heretofore, all candidates will be required to stand examination in both branches of the specialty, regardless of the fact that the major part of their practice may be in one or the other branch of the specialty.

An applicant entering military service in the present national emergency and assigned to work in general surgery under conditions satisfactory to the credentials committee may receive credit toward the required special training up to a maximum of six (6) months, applicable toward his three years of special training. Emergency military service may be counted as years of practice.

3. Must make application for investigation of his credentials and a survey of his character.

4. Must assure the board that he is limiting his practice to obstetrics and/or gynecology and that he intends to continue to do so having limited for at least six (6) months before making application.

This board deprecates engagement in other fields of practice than that in which candidates profess to be specialists. The board does not exclude from examination, however, obstetricians or gynecologists who practice abdominal surgery and urology in the female, as well as breast surgery, because of the correlation of these activities.

The board has ruled that physicians who accept male patients in their private or other practice, for operative or other care, cannot be regarded as specialists in obstetrics and gynecology. Special certifying boards in general surgery and internal medicine have been organized and such individuals should apply to these boards.

5. Must have membership in the American Medical Association, or membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association.

6. Must be a citizen of the United States or Canada.

This board will not certify a candidate who is not a citizen of the United States or Canada, though he be a resident of either country. Former citizens of other countries must have taken out at least first papers for citizenship and must have been certified by either the National Board of Medical Examiners or licensed to practice medicine in the United States or Canada by a state or provincial board of licensure; and further, there will be required a probationary period of at least three (3) years from the date of licensure in the practice of medicine in these countries before such a candidate may be admitted to examination.

APPLICATION AND FEES

Application must be made on a special blank which will be furnished by the secretary's office, 1015 Highland Building, Pittsburgh, Pa., and must be forwarded with the other required credentials and the application fee to the secretary's office. The secretary cannot make any eligibility rulings. These are made only by the credentials committee after reviewing the candidate's formal application, which must be completely filled out and previously filed with the secretary.

Application fee.....\$15.00

Make checks payable to American Board of Obstetrics and Gynecology.

(Applications will not be considered for classification and action by the credentials committee unless accompanied by the application fee, which is not returnable.)

Applications and application fees must be in the office of the secretary at least ninety (90) days prior to the scheduled date of the examinations.

Applicants who fail to exercise the examination privilege within three (3) years of the date of filing the application are required to file a new application and to pay a new application fee.

Examination fee.....\$85.00

(Payable when the candidate is notified of acceptance for examination. Not returnable after the candidate has been officially accepted by the credentials committee and notified to report for examination, except if the candidate is prevented from appearing for examination because of induction into military service.)

Applicants declared ineligible for admission to examination may reopen their applications within one (1) year of the filing date without payment of an additional application fee.

Total fee.....\$100.00

The fees have been carefully computed on a basis of cost of examinations and are used entirely for administrative expenses. Examiners serve without compensation other than actual expenses.

ABOLISHMENT OF SENIOR AND JUNIOR (A AND B) GROUP CLASSIFICATIONS

Effective March 1, 1942 the requirements for all candidates will be uniform, as follows:

1. Completion of at least one year in a general rotating intern service in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association.

(A second year general internship is to be considered as one of a candidate's years of practice. No credit will be given toward special training during a second year general internship.)

2. A minimum of seven (7) years of practice after the intern year, including at least three (3) years of special training in obstetrics and/or gynecology satisfactory to the board of directors.

3. Limitation of practice to obstetrics and/or gynecology. The candidate's practice must have been so limited for a period of at least six (6) months prior to the date of making application.

(Emergency military service or any other similar patriotic service, such as work with Selective Service boards, etc., will not be construed as nonlimitation of practice in violation of the board regulations.)

EXAMINATIONS

Applicants not qualifying before the 1942 examinations, as well as those who have previously applied and been accepted but have failed to appear for examination, and also those previously examined and failed will be subject to the new plan of general grouping and uniform examination after the final examination in June 1942.

Candidates accepted for examination after this year's class will be required to attain a passing grade in both a written examination and a review of case records (Part I), before becoming eligible for the oral clinical, and pathological examination (Part II).

Part I examinations are scheduled annually for the first Saturday of January. Application on an official application form, for admission to this examination must be filed in the office of the secretary with the application fee of fifteen dollars (\$15) at least ninety (90) days prior to this date. Grades cannot be mailed from the secretary's office until about March 15.

Arrangements will be made for candidates to report in any convenient city where there may be a diplomate of this board to conduct or supervise the written examination sent out under sealed cover from the board's office.

Applicants have three years from date of filing to appear for examination. After that time a new application with its fee is required.

Examination consists of:

1. A comprehensive written examination, given once yearly, including questions on both obstetrics and gynecology, as evidence of a fundamental knowledge of both branches is required of all candidates.

2. The filing of twenty-five (25) case reports in abstract form, to be presented by each candidate with the written examination paper to the local examiner, at the annual Part I examination. These must be of cases for which the candidate was personally responsible.

(The regulations regarding case records are newly revised ones, both in respect to reduction in number from fifty to twenty-five and to their preparation in abstract rather than in complete detail. For specific instructions regarding these new regulations see "Case Reports.")

No candidate is eligible for the general oral clinical, and pathological examinations (Part II) until he has passed the written portion and his case reports have been found satisfactory. The passing grade for the written examination and case reports is 75 per cent, and a candidate whose grade in either or both falls below 75 per cent is conditioned. Either or both of these conditions must be removed before the candidate is eligible for Part II.

Reexamination for the removal of conditions in Part I may be taken at any regular Part I examination after one year but within three years after the first failure without payment of an additional fee.

Candidates who successfully complete the Part I examination proceed automatically to the Part II examination held later in the year.

Part II. The general oral clinical, and pathological examinations given all candidates are conducted by the entire board and the assistant examiners near the time and place of the annual meeting of one or more of the national societies represented on this board, usually that of the American Medical Association.

Examination consists of:

1. Oral examination before from two to four examiners. An endeavor is made to adapt the details of the oral examination to each candidate's experience and practice, and the examination is particularly directed to ascertain his familiarity with recent obstetrical and gynecological literature, the breadth of his clinical experience, and his general qualifications as a specialist in obstetrics and gynecology.

2. Pathology examination. The candidate is expected to identify and discuss several obstetrical and gynecological pathological specimens and histologic sections.

As heretofore, all candidates will be required to stand examination in both branches of the specialty, regardless of the fact that the major part of their practice may be in one or the other branch of the specialty.

Examiners report orally upon each candidate to the assembled board, after which the results of their examinations are considered jointly by the entire board and assistant examiners. After a general consideration of the details of the candidate's oral and pathology examinations, including a review of his capability and general adaptability, the candidate is passed or failed by the entire board. No conditions are given in Part II of the examination. When a candidate fails in Part II of the examination, he is not required to repeat Part I, but to take a reexamination in the oral clinical, and pathological portions only. Reexamination may be taken within three (3) years of the original examination or first failure without payment of an additional fee.

CASE REPORTS

Particular attention is directed to this section, because of the new requirements regarding case records which go into effect in 1942.

Twenty-five (25) reports of operative obstetrical and gynecological cases are required. Nonoperative cases are not acceptable.

These reports must be of cases treated within four (4) years of the date of the candidate's application. The number of cases from one's residency service should not be more than half the total number.

The group of reports must include a variety of material rather than a number of cases of one type.

These reports should be prepared in abstract form in line with the following items:

1. Hospital admission number and date, with identifying initials, or name, of each patient, and name of operator (candidate), at the top of the page.

2. (a) Preoperative diagnosis, and basis for this, in brief.

- (b) Postoperative diagnosis, based on findings.

3. Nature of operation, omitting descriptive technical details, but including pathologist's findings on tissue removed.

4. Critical summary or analysis of cases, with critical deductions derived from correctness or incorrectness of diagnosis, operative findings, postoperative course, and from final results on discharges from hospital and at six months "follow-up" examination.

5. Two (2) separate index lists must accompany these reports, including name of hospital, admission manner, dates, identifying initials, or name of all twenty-five patients, with verifications of these and of the fact that the candidate was the operator, duly attested by the hospital superintendent or the medical director. The candidate's name must appear at the head of these lists.

Preparation of Reports. These are not to be copied verbatim from hospital records, but must be sufficiently complete so that the examiner can evaluate the judgment of the candidate in his choice of procedure.

Each report must include the items listed above, and again below:

1. Heading each separate case report must be the hospital number, name of the hospital at which the patient was operated upon, with all pertinent dates, together with the candidate's name.

2. Histories must be typewritten on standard size paper, 8½ by 11 inches.

3. Must be assembled by individual cases.

4. Must not be bound with any form of binding other than light weight paper folders or covers.

Obstetrical case reports should show:

1. Date of first prenatal visit and any special features bearing on the case.

2. The weight and condition of the child at birth and at time of discharge from the hospital.

Obstetrical reports which omit measurements of the pelvis inlet and outlet will be considered incomplete.

A final statement must be prepared for each case and must include:

1. An account of the candidate's personal observations of the case both prior to and subsequent to operation.

2. The basis for the diagnosis.

3. The facts that determined the course of treatment.

4. Critical conclusions to be drawn from the outcome of the case.

Case reports which do not include such discussion and comments will not be reviewed or graded by the examiners.

Two (2) complete index lists of these reports must accompany the records.

Separate lists must be made for each individual hospital at which operations were performed. These must state:

Candidate's name at head of each page.

Name and address of the hospital.

Patient's name.

Patient's admission number.

Date of admission.

Date of operation.

Date of discharge.

Lists must be verified by the superintendent or by the medical director, of each individual hospital from which the reports come. All verifications must be formally signed by the responsible hospital official.

Case reports submitted should be of patients treated within four (4) years of the date of the candidate's application.

The final action of the board is based upon the candidate's professional record, training and attainments, as well as on the results of his formal examination.

REVOCATION OF CERTIFICATES

Each Certificate of Qualification may be revoked by this board in the event that:

1. Any representation or statement made to the board or to any of its representatives by the physician so certified, including the statements contained in his application for certification, shall have been false or intentionally misleading.

2. The physician so certified shall not *in fact* have been eligible to receive certification, irrespective of whether or not the facts constituting such ineligibility were known to or could have been ascertained by this board, its members, directors, examiners, officers, or agents at or before the time of issuance of such Certificate of Qualification.

3. Any rule governing examination for certification shall have been violated by the physician so certified and the fact of such violation shall not have been ascertained until after the issuance of the Certificate of Qualification.

4. The physician so certified shall fail to abide by the regulations governing the limitation of his practice to the specialty as hereinabove defined.

5. The physician so certified shall violate the standards of ethical practice of medicine then accepted by organized medicine in the locality in which he shall be practicing and, without limitation of the foregoing, the forfeiture, revocation or suspension of his license to practice medicine, or the expulsion from, or suspension from the rights and privileges of membership in, the American Medical Association or any state or county society affiliated therewith, any recognized Canadian medical society, the American Association of Obstetricians and Gynecologists and Abdominal Surgeons or the American Gynecological Society shall be conclusive evidence of a violation of such standards of ethical practice of medicine.

6. The physician so certified shall fail to comply with or violate, or the issuance or receipt by him of such Certificate of Qualification shall have been contrary to or in violation of, the Certificate of Incorporation, the By-Laws or the Rules and Regulations of this board.

Upon revocation of any Certificate of Qualification by this board as aforesaid, the holder thereof shall return his Certificate of Qualification and all other evidence of certification to the secretary of the board and his name shall be removed from the list of diplomates or certificate holders by this board.

Make checks payable to the American Board of Obstetrics and Gynecology. Communications should be addressed to the secretary-treasurer.

SUPPLEMENT

GROUP CLASSIFICATION EFFECTIVE UNTIL MARCH 1, 1942

Classification of candidates in Groups A and B will continue in effect for and until the 1942 examinations under former existing regulations. Following that time new regulations finally adopted by the board at its 1941 meeting will be in force.

Group A consists of those who have limited their practice to obstetrics and/or gynecology for a period of ten years or more, having had adequate special training following a one year general internship.

Applications for this group will be accepted until March 1, 1942, or ninety (90) days prior to the annual general examination in June 1942.

Group B consists of those who have had:

1. At least one year of intern service in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association. A second year internship is to be considered as one of a candidate's years of practice. No credit will be given toward special training during a second year general internship.

2. Five years or more practice thereafter, including at least three years of special training in obstetrics and/or gynecology satisfactory to the Board of Directors.

3. Who have been limiting their practice to obstetrics and/or gynecology for at least six months prior to filing an application.

Opportunity for personal responsibility during this period of training is highly desirable.

Application for Group B will be accepted until Oct. 1, 1941, or until ninety (90) days prior to the scheduled date for the written examination and submission of case records, namely Jan. 3, 1942.

An applicant entering military service during the present national emergency and who is assigned to general surgery under conditions satisfactory to the Credentials Committee shall receive credit toward the required special training up to a maximum of six (6) months applicable toward his three years of special training.

EXAMINATION DETAILS

Applicants who qualify under Group A shall be required to undergo and pass a practical oral clinical and laboratory examination, including obstetrical and gynecological pathology. (After March 1, 1942 case records and written examinations will also be required as at present for Group B.) As heretofore, all candidates will be required to stand examination in both branches of the specialty, regardless of the fact that the major part of their practice may be in one or the other branch of the specialty.

Applicants who qualify under Group B shall be required to take and pass a written clinical and laboratory examination in obstetrics and gynecology, including, obstetrical and gynecological pathology, as well as the general oral clinical examination. Each candidate shall submit fifty (50) typewritten case records of major pathological obstetrical and/or gynecological cases with or without operative procedures. In both obstetrical and gynecological case histories not more than ten (10) major selected nonoperative cases may be included.

When pathological tissue is removed, adequate gross and microscopic descriptions are required. The candidate and the pathologist are required to employ the accepted nomenclature in the classification of gross and microscopic reports of pathological findings.

It is preferable that case records submitted be of patients treated within four (4) years of the date of the candidate's application. It is preferable also that the number of residency cases submitted should not be more than half (25) of the total number of fifty (50) cases required.

CASE RECORDS

Case histories need not be copied verbatim from the hospital records, but must be sufficiently complete so that the examiner can determine the diagnosis of existing conditions and evaluate the judgment of the candidate in his choice of procedure. Each history must give the hospital number and name of the hospital at which the patient was treated or operated upon, together with all pertinent dates. Histories must be typewritten on standard size paper, 8½ by 11 inches, assembled by individual cases, and submitted without any form of binding other than light weight paper folders. The following data should be as complete as possible: essential diagnosis, and in operative cases preoperative diagnosis; ample summary of operative procedure; clinical and pathological diagnosis; summary of postoperative course with special reference to morbidity; findings at time of discharge from hospital and at six months "follow-up."

The obstetrical case reports should show the date of the first prenatal visit and any special features bearing on the case. The examination of obstetric patients should include a routine serologic test for syphilis; also blood grouping or typing should be noted on histories of patients requiring transfusions. The weight and condition of the child at birth and at the time of discharge from the hospital should be shown on the obstetric history.

A final statement must be prepared for each case, to include an account of the candidate's personal observations of the case both prior to and subsequent to operation. These data must include:

1. The basis for the diagnosis.
2. The facts that determined the course of the treatment.
3. Critical conclusions to be drawn from the outcome of the case.

Case reports which do not include such discussion and comments will not be reviewed by the examiners. Obstetrical histories which omit measurements of the pelvic inlet and outlet will be considered incomplete.

The group of histories must include a variety of material rather than a number of cases of one type. The histories should be sufficiently detailed so that the examining board, after a careful reading of the reports, will be able to answer the following questions:

1. Is the diagnosis warranted by the recorded data?
2. If not, how lacking?
3. Are the indications for operation clearly stated?
4. Is the technique satisfactorily described?
5. Do the results justify the procedure?
6. Do the conclusions drawn indicate a grasp of the subject?

Only those reports which carry the candidate's personal deductions, conclusions and comments will be credited toward the fifty, and these reports must be diversified. Case reports which do not conform to board regulations will not be graded.

Note: Two (2) complete index lists of these cases must accompany the reports. Separate lists should be made for each individual hospital at which operations were performed. These lists must state the candidate's name at the head of each page, the name and address of the hospital, the name of the patient, admission number, date of admission, date of operation, and date of discharge. The candidate must have these lists verified by the superintendent, or the medical director of each individual hospital from which these case reports come. All verifications must be formally signed by the responsible hospital official.

Case histories are to be presented with the completed examination paper to the examiner conducting the written examination. They are not to be sent by the candidate to the secretary.

The final action of the board is based upon the candidate's professional record, training and attainments, as well as on the results of his formal examination.

Group B candidates cannot be notified of the results of their written examination and review of case reports until about March 15.

AMERICAN BOARD OF OPHTHALMOLOGY

CONRAD BERENS, Chairman, New York.

WILLIAM L. BENEDICT, Vice Chairman, Rochester, Minn.

JOHN GREEN, Secretary-Treasurer, 6830 Waterman Avenue, St. Louis.

DANIEL B. KIRBY, Assistant Secretary, New York.

EDWARD C. ELLETT, Memphis, Tenn.

GRADY E. CLAY, Atlanta, Ga.

WALTER B. LANCASTER, Hanover, N. H.

ALLEN GREENWOOD, Boston.

FREDRICK C. CORDS, San Francisco.

S. JUDD BEACH, Portland, Me.

GEORGIANA M. DVORAK THEOBALD, Oak Park, Ill.

CECIL S. O'BRIEN, Iowa City.

ORIGIN, AIMS AND METHODS

In 1913 the American Ophthalmological Society, the Section on Ophthalmology of the American Medical Association, and the American Academy of Ophthalmology and Otolaryngology appointed committees to report on ophthalmic education.

In 1914 these committees recommended that medical schools of the first class establish graduate courses in ophthalmology leading to an appropriate degree, and that these courses should represent not less than two years of systematic work subsequent to taking the degree of Doctor of Medicine. There was unanimous agreement as to the need of systematized and standardized training of those who are to practice ophthalmology, but it was clear that, in the near future, the number who would take the complete course leading to such a degree would be small. Moreover, such a course would not solve the problem of differentiating, in some degree, between the competent and the incompetent among those now in practice in ophthalmology. The committees were continued and, in 1915, they made further recommendations, as a result of which a joint board was created consisting of three representatives from each of the three special societies.

In 1916, after much preliminary work, this board was organized as the American Board for Ophthalmic Examinations (later changed to "American Board of Ophthalmology"). It was incorporated May 3, 1917.

In 1934 the plan of organization was changed so that each component society elects four members, instead of three, to form the board. The members of this board are chosen in the same manner as the presiding officers of these societies are chosen. One is elected each year by each of the societies represented on the board, to serve for four years.

As other specialties formed boards similar to the American Board of Ophthalmology the need for some supervising and coordinating control led to action by the American Medical Association in 1933 authorizing the Council on Medical Education and Hospitals: (1) to formulate standards of administration, based on those of the American Board of Ophthalmology, of Otolaryngology, of Gynecology and Obstetrics, and of Dermatology and Syphilology; and (2) to recognize officially new boards meeting these standards.

The Constitution of the Advisory Board for Medical Specialties which was organized in 1934 states that: "This board shall act in an advisory capacity to such organizations as may seek its advice concerning the coordination of the education and certification of medical specialists."

CHIEF FUNCTIONS

1. To establish standards of fitness to practice ophthalmology cooperating with hospitals and graduate schools of medicine.

2. To arrange and conduct examinations to test the qualifications of those who practice ophthalmology, and to confer certificates upon those who meet the standards established by the board.

3. To act as preceptors for prospective students of ophthalmology.

NO DEGREES

The conferring of a degree is left to the universities, where it belongs, and the board makes no attempt to control the practice of ophthalmology by any license or legal regulation whatever. It simply aims to establish a standard of fitness to practice ophthalmology, and to certificate any who, voluntarily, apply and satisfy the board of their qualifications.

The following is the wording of the present certificate:

The American Board of Ophthalmology hereby certifies that(name)..... has pursued an accepted course of graduate study and clinical work, and has successfully passed

the examination in ophthalmology conducted under the authority of this Board.

Date.....

Signatures of members of the Board

Many special eye hospitals as well as general hospitals in all parts of the country require the certificate for appointment or promotion on their staffs. In addition, many societies now require the certificate as a prerequisite for membership.

The number of institutions and societies which require the certificate of the board is increasing.

The American College of Surgeons recognizes the certificate of this board as evidence of academic fitness in ophthalmology. It requires from candidates for its Fellowship who hold such certificates only half as many case histories as from those who are not so certificated.

Up to July 1, 1941 approximately 1,875 ophthalmologists have received the certificate of the board.

FEES

The fee for the examination and the certificate of the American Board of Ophthalmology is \$50. Of this sum \$25, which is not returnable, must accompany the application. The balance of \$25 must be paid when the certificate is ready for issuance.

If a candidate fails in the written examination, he may be admitted to a second examination within three years, for which there will be an additional fee of \$10.

Applications expire three years from date of application. If a candidate has not appeared for examination before expiration of his application, he will be required to apply again and pay an additional application fee of \$25.

The fees of candidates are used solely for defraying the actual expenses of the board. The members of the board and their associates receive no emoluments.

GENERAL REQUIREMENTS FOR ALL CANDIDATES

1. Application on special blank, which may be obtained from the secretary, must be filled out accurately. Letters of endorsement from two well known physicians (preferably ophthalmologists) together with any other required credentials must accompany the application and must be sent to the secretary at least before December 1 preceding date when the candidate expects to appear for the written examination.

2. The candidate must have high ethical and professional standing in his community.

3. Membership in the American Medical Association or such other societies as are recognized for the purpose by the Council on Medical Education and Hospitals of the American Medical Association. In the case of an applicant whose training has been received outside of the United States and Canada, his credentials must be satisfactory to the board; if he has been in practice less than ten years he should obtain the certificate of the National Board of Medical Examiners.

4. A list of papers or books published by the candidate must be submitted.

5. Reports of ten cases of varied character which have been observed and treated by the applicant are required.

6. An examination divided into Part I (written) and Part II (clinical, practical and laboratory). In both of these examinations a knowledge of the practical application of the basic sciences of ophthalmology will be required.

7. Citizenship in country where candidate practices.

The final action of the board is based on the candidate's professional record, training and attainments as well as on the results of his formal examinations.

GENERAL EDUCATIONAL REQUIREMENTS

(Applicable as far as possible after 1944)

1. A degree from a medical school of high standing satisfactory to the board and approved by the Council on Medical Education and Hospitals of the American Medical Association. In the case of an applicant whose training has been received outside of the United States and Canada, his credentials must be satisfactory to the board. He may be required to obtain the certificate of the National Board of Medical Examiners.

2. Completion of an internship of not less than one year in a hospital approved by the same Council.

SPECIAL TRAINING

(Applicable as far as possible after 1944)

A period of combined study, training and practice of not less than three years in approved medical schools, hospitals, clinics, dispensaries, laboratories, preceptorships and private practice.

(A total of five years will be required of candidates practicing eye, ear, nose and throat.)

1. This shall include graduate study of the basic medical sciences which are fundamental to the intelligent practice of ophthalmology, particularly: anatomy, histology, embryology, optics, physiologic optics, visual physiology and psychology, pathology, bacteriology, pharmacology. Mere factual knowledge of these subjects is not sufficient. The candidate must have had training in their application and in their use in clinical ophthalmology, especially in refraction, disorders of motility and binocular vision, perimetry, and in the skilful adjustment and use of instruments such as the ophthalmoscope, retinoscope, slit lamp and microscope.

2. Active clinical experience in approved hospitals, clinics, dispensaries and private practice. Library and laboratory facilities should be utilized for the intensive study of cases.

The subject matter to be covered under 1 and 2 is outlined in the syllabus prepared by the board.

These requirements may be met in various ways:

BASIC STUDIES

A—By courses in approved graduate medical schools.

B—By the opportunities for study afforded by the appointment to a junior position in one of the departments with attendance at advanced lectures in the other subjects.

C—By advanced study of these subjects while a resident and by application of the principles involved to patients under one's control.

D—By the detailed study, under supervision or as assistant to an experienced research worker, of some problem or topic which brings the basic facts of physiology, pathology, etc., into direct relation with the concrete clinical problem. The analysis of a problem with detailed knowledge of its fundamental physiologic and pathologic background does much to stimulate thoroughness, clear thinking and progress.

CLINICAL EXPERIENCE

A—By residency in an approved hospital. The most desirable of these residencies have regular lectures covering the whole field of clinical ophthalmology and of the basic subjects as applied in clinical practice. Many of these have seminars at which residents report cases which they have carefully worked up. These are discussed by the other residents and by the staff and the method of presentation as well as the subject matter critically considered.

B—There are many residencies, usually of 12 months, which do not furnish regular instruction by lectures and quizzes and seminars. If he has access to a good library and laboratory, the student can learn a great deal and has some advantages over the man who expects to be "spoon-fed." The syllabus prepared by the board will guide him in his selection of topics to be studied.

C—There are some opportunities to continue the study and experience by securing appointments as fellows.

D—By a period of training in association with a well trained and critical ophthalmologist who takes the trouble to teach and guide his assistant.

E—After completing a residency it is of great advantage to secure a position in a clinic as fellow or assistant. This may require only part time work, but due credit will be given. Its value to the student depends on how much study he puts into it and on how competent his seniors are.

F—Research under competent critical and sympathetic supervision will give first hand insight into (1) the methods whereby old knowledge was and new knowledge is acquired, and (2) the pitfalls which accompany attempts to enlarge the sphere of knowledge. Only in this way can the candidate evaluate facts of the past and present in the intelligent critical way which is expected of the specialist.

The candidate who cannot secure the type of residency he desires should not despair, for his progress depends far more on how he uses his opportunities than on the opportunities themselves.

WHAT CONSTITUTES THE EXAMINATION

In determining the question of certification, the examiners rely on the following criteria:

1. The applicant's professional and ethical record;
2. Case reports;
3. Written examination;
4. Practical clinical and laboratory examination.

CASE REPORTS

Detailed instructions for the preparation of case reports should be obtained from the secretary.

WRITTEN EXAMINATION: PART I

The written examination may be given simultaneously in as many cities as the board may determine suitable for the purpose. A candidate, to be eligible for Part I, must meet all general requirements. Arrangements will be made for candidates to report in a convenient city where there may be a board member, or an associate member, to conduct and supervise the written examination.

These examinations will not be given at the time of the oral and clinical examination or board sessions but will be held at least sixty days before such examinations simultaneously in different parts of the country at places reasonably convenient to candidates.

No candidates shall be eligible for the practical examination until he has passed the written examination and his case reports have been found satisfactory. In the event of failure in either or both of these preliminary tests, a candidate is conditioned and the conditions must be removed before the candidate is eligible to appear for the practical (Part II) examination.

The written examination questions will be on all subjects as follows:

External Diseases.	Perimetry and Campimetry
Ophthalmoscopy	Relation of the Eye to General
Pathology-Histopathology	Diseases
Refraction and Retinoscopy	Therapeutics and Operations
Anatomy and Embryology	(including Practical Surgery)
Ocular Motility	Optics and Visual Physiology

Written examination papers will be reviewed by examiners who reside in districts remote from those in which the candidate practices.

PRACTICAL AND CLINICAL EXAMINATION: PART II

The purpose of the examination is to determine the competence of the candidate to practice ophthalmology.

Candidates must be prepared to be examined in the whole field covered by the syllabus of the board. The time spent in preparation will count less than the knowledge and experience acquired as shown on examination.

The subdivisions of the practical examination are as follows:

1. External diseases of the eye, lacrimal passages, etc., including inspection, focal illumination, use of loupe and slit lamp, examination of reactions of the pupil, of tension by tonometer and by fingers.

2. Ophthalmoscopy. Several patients will be examined by the candidate and the findings described or drawn. The ability to see with the ophthalmoscope and to interpret what is seen, and the systematic and thorough methods of examination used by the candidate will count for more than mere statement of diagnosis. A candidate should bring his own ophthalmoscope so that he may not suffer the handicap of an unfamiliar instrument.

3. Pathology. The candidate should be familiar with general clinical pathology as well as the etiology, pathology, and bacteriology of diseases of the eye. He will be asked to examine microscopic slides and to recognize ordinary normal and pathologic histology of the eye and to identify the commoner microorganisms.

4. Refraction. A candidate will examine patients and show mastery of various methods, and of the principles of refraction and of retinoscopy. He should bring his own retinoscope.

5. Ocular Motility. The candidate will demonstrate upon patients his familiarity with routine methods of examination for abnormalities of the ocular muscles.

6. Practical Surgery. A candidate will demonstrate his surgical technic upon animals' eyes. To have the advantage of using instruments with which he is familiar, he should bring his own equipment for performing a regular combined extraction of the lens.

DATES OF PART II EXAMINATION

Examinations will be held annually at or near the time and place of the meeting of the American Medical Association; also at other times and places at the discretion of the board, depending on the number of applications from any region.

Notices of all examinations will be found in The Journal of the American Medical Association, and in the special journals of ophthalmology.

REEXAMINATION

Candidates may be reexamined as often as they desire, provided they give satisfactory evidence of adequate preparation. One year must elapse between examinations and the board may, at its discretion, deny the candidate the privilege of reexamination.

REVOCATION OF CERTIFICATE

Any certificate issued by the board shall be subject to revocation by the board at any time in case it shall determine in its sole judgment that a candidate, who has received the certificate

of the American Board of Ophthalmology, either was not properly qualified to receive it, or has since its receipt become disqualified.

PREPARATORY GROUP

In establishing a preparatory group of prospective candidates for its certificate, the American Board of Ophthalmology plans to assist physicians who wish to study ophthalmology so that they will be acceptable as candidates for examination and certification when they have completed the requirements.

Any graduate or undergraduate of an approved medical school is eligible to make application for membership in this group. Candidates so applying will be notified officially by the secretary when the board has accepted their applications. If accepted, data will be sent concerning ethical and educational requirements. Syllabuses and other information will be made available to them. The board desires to help candidates improve their opportunities so that they will be fully prepared for the examination.

It is essential that candidates conduct themselves in an entirely ethical manner so that they will bring honor to the profession.

Information and counsel will be available at all times to accepted candidates in this group through advisers who are members or past members of the board.

Members of the preparatory group must keep a summarized record of their activities, two copies of which will be sent to the secretary in January of each year and will be incorporated in the final application for examination and certification.

The fee for application for membership in the preparatory group is \$10. This will be deducted from the \$50 which is required of every candidate for examination. When the candidate makes application for the examination, he will be required to pay \$25, and the balance of \$15 must be paid when the certificate is issued. No fees will be refunded.

It is of increasing importance that a physician specializing in diseases of the eye obtain the certificate of the American Board of Ophthalmology. The American Medical Association will especially designate certificated ophthalmologists in future directories. A special directory of all certificated specialists will be published by the Advisory Board for Medical Specialties.

Many national and local ophthalmologic societies demand the certificate of the American Board of Ophthalmology before admission. Promotion in many hospitals cannot be obtained unless the applicant holds the certificate of the board.

For sufficient reason, a person enrolled in this preparatory group may be dropped by vote of the board.

Communications should be addressed to the secretary-treasurer.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY, Inc.

FREMONT A. CHANDLER, President, Chicago.

JOHN C. WILSON, Vice President, Los Angeles.

GUY A. CALDWELL, Secretary-Treasurer, 3503 Prytania Street, New Orleans.

GEORGE E. BENNETT, Baltimore.

FRANK D. DICKSON, Kansas City, Mo.

MELVIN S. HENDERSON, Rochester, Minn.

SAMUEL KLEINBERG, New York.

J. SPENCER SPEED, Memphis, Tenn.

PHILIP D. WILSON, New York.

INTRODUCTION

The rapid growth of specialization and the increasing number of physicians limiting themselves in their practice to one branch of medicine or surgery emphasize the need for the proper certification of specialists in the various branches of the medical science. In recognition of this condition the American Board of Orthopaedic Surgery, Inc., aims to elevate the standard of qualifications for the practice of orthopaedic surgery and to certify those surgeons who voluntarily comply with its requirements.

In order to place orthopaedic surgery on the highest possible plane, the American Orthopaedic Association, the Section on Orthopaedic Surgery of the American Medical Association and the American Academy of Orthopaedic Surgeons united in organizing a certifying board which was incorporated in the year 1934 as the American Board of Orthopaedic Surgery, Inc.

The American Board of Orthopaedic Surgery, Inc., has been officially approved by the Advisory Board for Medical Specialties and by the Council on Medical Education and Hospitals of the American Medical Association.

WHAT THE BOARD WILL ACCOMPLISH

1. Certification by the board will establish a criterion to both interested lay and professional groups for judging the qualifica-

tions of an orthopaedic surgeon. Thus a reliable guide will be furnished for the choosing of consultants.

2. Hospitals and other organizations will no doubt establish rules limiting service on their permanent staffs to those certified by the board.

3. It will gradually tend to limit the practice of orthopaedic surgery to those properly qualified.

4. Certification by the American Board of Orthopaedic Surgery is one of the essential requirements for membership in the American Orthopaedic Association and the American Academy of Orthopaedic Surgeons.

Excerpts from Articles 1, 2, 7 and 8 of the By-Laws.

Article 1. *Section 1. DEFINITION.* Orthopaedic Surgery is that branch of surgery especially concerned with the preservation and restoration of the functions of the skeletal system, its articulations and associated structures.

Article 2. *Section 2. PURPOSES.* To test and determine the qualifications of applicants for registration and to issue certificates to those found qualified.

Section 3. To prepare and maintain a registry of the holders of the certificates issued by the board.

Section 4. To serve the public, physicians, hospitals and medical schools by furnishing lists of those who have received the certificate of the board, and thus to assist in protecting the public against irresponsible and unqualified practitioners who profess to specialize in orthopaedic surgery.

Article 7. *Section 1. APPLICATION FOR CERTIFICATE.* Each application for a certificate shall be filed with the secretary upon the prescribed form, and shall be accompanied by the fee which the board may fix from time to time. It shall also be accompanied by an unmounted autographed recent photograph of the applicant and the names of two orthopaedic surgeons acceptable to the board, who may be referred to for information in regard to the applicant.

Section 2. The applicant must have the following qualifications:

(a) He must be a graduate of a medical school approved by the Council on Medical Education and Hospitals of the American Medical Association.

(b) He must be of high ethical and professional standing.

(c) He must be a citizen of the United States or Canada.

(d) He must be duly authorized to practice medicine in the state or province of his residence.

(e) He must be a member of the American Medical Association or another society approved by the Council on Medical Education and Hospitals of the American Medical Association.

(f) He must have had one year of internship in a general hospital acceptable to the board.

(g) After Jan. 1, 1940, he must have had three years of concentrated instruction in orthopaedic surgery approved by and acceptable to the board. (A residency of at least two years on an orthopaedic service of a hospital recognized by the Council of the American Medical Association is desirable.)

(h) He must have knowledge of the basic medical sciences related to orthopaedic surgery.

(i) He must have had at least two years' further experience in the actual practice of orthopaedic surgery. Continuation of training (g) beyond the three years required will not be considered as actual practice unless the position of the candidate is considered permanent or his responsibilities equivalent to those encountered in private practice. This means that interns, residents, fellows, graduate students and assistants will not be credited with additional periods of training unless they are permanent members of the organizations with which they are associated.

(j) He must have limited his work to the field of orthopaedic surgery for at least two years prior to the submission of his application for examination.

(k) In the case of an applicant whose training has been received outside of the United States and Canada, his credentials must be satisfactory to the Council on Medical Education and Hospitals of the American Medical Association and to the National Board of Medical Examiners. In addition, he must have been engaged in the practice of orthopaedic surgery in the United States (or Canada) for at least three years prior to the submission of his application.

(l) During the present national emergency, the board will recognize up to a maximum of one year for work done in the orthopaedic division of the Army or Navy. If the above fills

out the three years of special required training for examination, further time spent in the orthopaedic division of the armed forces, up to a maximum of one year, will be credited towards the practice requirement.

Section 3. Each applicant shall be examined and his qualifications determined by the board in such manner as it may designate, and his record shall be reviewed by the board in the light of all assembled information.

Article 8. Section 1. CERTIFICATE. If the applicant be found qualified therefor, a certificate that he has been found by this board qualified to practice orthopaedic surgery shall be issued to him. The certificate shall be in such form as may be adopted by the board, and shall be signed by the officers and members of the board.

EXAMINATION

Examinations will be held once or twice a year. If feasible, these examinations will be in conjunction with meetings of the major orthopaedic societies.

Oral and written examinations will be held on clinical, anatomical and pathological phases of orthopaedic surgery. Anatomical and pathological laboratories and hospital wards will be used when practicable.

APPLICATION FOR CERTIFICATION

Application forms may be obtained from the secretary of the board. These should be filled in accurately and returned not less than ninety days prior to the next examination. An autographed photograph and the fee must accompany the application.

FEES

The examination fees have been adjusted so as to be in closer accord with the other specialty boards. A fee of \$50 will accompany the application and cover the expenses of the first examination. Candidates appearing before the board for second and third examinations will pay additional fees of \$25 for each of the subsequent examinations following the first. This will take effect as of Jan. 15, 1941 and will not be retroactive.

ORIGIN, AIMS AND METHODS

SOURCE OF AUTHORITY

In 1916 the American Academy of Ophthalmology and Otolaryngology appointed a committee on examinations, consisting of Drs. Thomas E. Carmody, Harris P. Mosher and Ross Hall Skillern, before whom new members professing otolaryngology as their sovereign work, were to appear to be qualified as such.

In 1924, through the persistent efforts of Dr. George Shambaugh, this activity was enlarged to include representatives from the American Otological Society; the American Laryngological Association; the American Laryngological, Rhinological and Otological Society; the American Academy of Ophthalmology and Otolaryngology; and the Section on Laryngology, Otology and Rhinology of the American Medical Association. Each organization appointed two members, making a total of ten, which constituted the first American Board of Otolaryngology.

Dr. T. H. Halsted of Syracuse, New York, and Dr. H. W. Loeb of St. Louis were appointed to represent the American Otological Society; Dr. H. P. Mosher of Boston and Dr. R. H. Skillern of Philadelphia were appointed to represent the American Laryngological Association; Dr. B. R. Shurly of Detroit and Dr. F. R. Spencer of Boulder, Colorado, to represent the American Laryngological, Rhinological and Otological Society; Dr. T. E. Carmody of Denver and Dr. W. P. Wherry of Omaha to represent the American Academy of Ophthalmology and Otolaryngology; and, Dr. J. C. Beck of Chicago and Dr. R. C. Lynch of New Orleans to represent the Section on Laryngology, Otology and Rhinology of the American Medical Association.

CHIEF ACTIVITIES OF THE BOARD

First. To establish standards of fitness to practice otolaryngology.

Second. To arrange, control and conduct examinations to test the qualifications of those who desire to practice otolaryngology and to confer a certificate on those who meet the established standards.

These activities proceed from the object of the corporation which is stated in the Articles of Incorporation to be:

"The object of the corporation shall be to elevate the standard of otolaryngology, to familiarize the public with its aims and ideals, to protect the public against irresponsible and unqualified practitioners, to receive applications for examination in otolaryngology, to conduct examinations of applicants, to issue certificates of qualification in otolaryngology and to perform such duties as will advance the cause of otolaryngology."

NO DEGREES

The conferring of a degree is left to the universities, where it belongs, and the board makes no attempt to control the practice of otolaryngology by efforts to promote any license or legal regulation whatever. It simply aims to establish a standard of fitness to practice otolaryngology, and to certify those who voluntarily apply and satisfy the board of their qualification.

VALUE OF CERTIFICATE

The five national otolaryngological associations responsible for the organization of the board are sponsoring its activities. Four of these associations require the board certificate from each applicant for membership.

Other important societies and organizations are following the example of these influential organizations. Moreover, the certificate of the board is required of candidates for appointments in many and various important positions in hospitals, colleges, etc. It is expected that the medical public and the lay public will learn to discriminate between those who are well fitted and those who are not, and will be influenced by the certificate of the board in arriving at their conclusions.

CLASSIFICATION OF CANDIDATES

Applicants for examination and for the certificate of the board are divided into classes according to the length of time they have practiced otolaryngology.

(Limited practice in otolaryngology interpreted as 90% otolaryngological practice—ophthalmology excepted.)

Class I—Limited Practice—15 years or more.

Class II—Limited Practice—10 to 15 years.

Class III—Limited Practice—5 to 10 years.

Class IVA—Limited Practice—5 years.

Class IVB—Limited Practice—3 and 4 years.

(Only candidates having completed a satisfactory residency or an acceptable full academic year basic science course are eligible to IVB.)

REQUIREMENTS

UNTIL JAN. 1, 1942

The following general requirements are demanded by the board:

First. A candidate acceptable for the examination must be a graduate from a school approved by the Council on Medical

Education and Hospitals of the American Medical Association; furthermore, he must have at least one year of internship in an approved hospital.

Second. Membership in the American Medical Association or, by courtesy, membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association. Except as here provided, membership in other societies should not be required.

Third. In addition, a candidate must have completed at least three years graduate preparation for the specialty, at least one year (more desirably two) in a recognized residency or in basic courses and followed by private practice in otolaryngology.

Fourth. Five years of specialized practice will be accepted in lieu of the requirements of paragraph 3 until Jan. 1, 1942.

Fifth. Application must be made on a special blank procured from the secretary. It must be executed and returned to the secretary, together with other required credentials, sixty days in advance of the examination at which the candidate desires to appear.

Sixth. All applicants must send a small photograph with application and must present themselves in person before the board.

Seventh. Fee for the examination is \$50 and same must accompany application blank. No application will receive consideration until fee is paid.

Eighth. An application remains valid only five years—therefore, an applicant must appear for examination within this time or forfeit fee. The fee under no circumstances is returnable.

If the candidate fails in an examination he will be admitted to a second examination after one year, but within the regulation time limit of his application. Sixty days' notice of intention to appear is required. If a candidate who has failed does not appear before the expiration of validity of his application he will be required to make new application and pay additional fee of \$50 before reexamination.

An applicant having failed twice, must file a new application, pay an additional fee of \$50 and convince the board of additional postgraduate study previous to being assigned appointment for another examination.

Examinations covering two or three days will be held bi-annually at, or near, the time and place of meeting of the American Medical Association, and of the American Academy of Ophthalmology and Otolaryngology.

An extra examination is sometimes held provided the class of applicants is large enough to warrant it.

Candidates are required to sign the following pledge:

I hereby apply to the American Board of Otolaryngology for examination by the said board in accordance with its rules and herewith enclose the fee of fifty (\$50) dollars. I hereby agree that prior to an examination, or subsequent to my examination, the board may investigate my standing and reputation as a physician, including my reputation for complying with the standard of ethics of the profession, and may refuse to examine me, or, having examined me, may refuse a certificate, and such refusal to grant a certificate, whether justified or otherwise, may not and shall not be questioned by me in any court of law or equity or other tribunal, nor shall I have any claim, in the event of such refusal, to a return of the fee accompanying this application.

PRACTICAL EXAMINATION

1—Written examinations:

Class III, Class IVA and Class IVB.

2—Pathology:

Microscopy—Class IVA, Class IVB.

Gross—Class III, Class IVA and IVB.

3—Clinical examination of patients: To include history taking; physical and functional examinations; use of laboratory and x-ray findings; discussion of differential diagnosis; and discussion and defense of his findings, opinion and suggested management.

All classes.

4—Didactic examination to be a private, oral examination covering any aspect of otolaryngology and its interrelation with general medicine.

All classes.

Communications should be addressed to the secretary-treasurer.

AMERICAN BOARD OF PATHOLOGY, Inc.

A. H. SANFORD, President, Rochester, Minn.

FREDERICK H. LAMB, Vice President, Davenport, Ia.

FRANK W. HARTMAN, Secretary-Treasurer, Henry Ford Hospital, Detroit.

ALVIN G. FOORD, Pasadena, Calif.

NATHAN CHANDLER FOOT, New York.

HOWARD T. KARSNER, Cleveland.

ROY R. KRACKE, Emory University, Ga.

JOSIAH J. MOORE, Chicago.

ORGANIZATION AND OBJECTIVES

In June 1935 the Section on Pathology and Physiology of the American Medical Association and the American Society of Clinical Pathologists appointed committees which acted jointly in consideration of the feasibility and necessity of a national qualifying board. The joint committees agreed unanimously that such a board should be established and proceeded to draw up by-laws for such a board. In May 1936 the American Society of Clinical Pathologists and the Section on Pathology and Physiology of the American Medical Association accepted the proposed by-laws, authorized the nomination of four members each to the board and suggested incorporation in the state of Michigan. Approval of the board by the Advisory Board for Medical Specialties and the Council on Medical Education and Hospitals of the American Medical Association was given. On July 19, 1936, the organization of the board was carried out in Chicago.

PURPOSES

A. To encourage the study and promote the practice of pathology.

B. To elevate the standards and advance the cause of pathology, by encouraging its study and improving its practice.

C. To determine the competence of those wishing to practice this specialty of pathology and to arrange, conduct, and control investigations and examinations to determine the qualifications of such individuals who voluntarily apply for the certificates issued by the corporation.

D. To grant and issue certificates in the special field of pathology to voluntary applicants therefor and to maintain a registry of holders of such certificates.

E. To serve the public, the medical profession, hospitals, and medical schools by preparing and furnishing lists of specialists who have been certified by the corporation.

VALUE OF THE CERTIFICATE

Judging from the experience of other specialties operating a certifying board it is anticipated that the certificate will be of value in that the medical profession, the lay public, and hospital administrators will utilize certificates from the board as a means of discriminating between those that are thoroughly qualified in pathology and those that are not. Lists of those holding certificates will be made available from time to time by this board through the publication of the same in pamphlets and in national medical journals.

BOARD NOT AN EDUCATIONAL INSTITUTION

The board is in no sense an educational institution and the certificates of the board are not to be considered degrees. Therefore the certificate does not confer on any person legal qualifications, privileges, or license to practice medicine or the specialty of pathology. The board does not purport in any way to interfere with or limit the professional activities of any licensed physician. Its chief aim, as stated above, is to standardize the qualifications for the specialty of pathology and to issue certificates to those voluntarily complying with the requirements of the board.

GENERAL REQUIREMENTS

A. General qualifications.

1. Satisfactory moral and ethical standing in the profession.

2. License to practice medicine.

3. Membership or associate membership in the American Medical Association or by courtesy membership in such Canadian or other national medical societies as are approved by the Council on Medical Education and Hospitals of the American Medical Association is suggested.

4. That the applicant devotes his time primarily and principally to the practice of pathology.

B. Professional education.*

* NOTE: In case of an applicant whose education and/or training has been received outside the United States or Canada, his credentials must be acceptable to the National Board of Medical Examiners and the American Board of Pathology.

1. Graduation from a medical school in the United States or Canada, approved by the Council on Medical Education and Hospitals of the American Medical Association.

C. Special training, to be effective after July 1, 1938:

1. Completion of an internship of not less than one year in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association.

2. A period of study, exclusive of internship, of not less than three calendar years, exclusive of reasonable vacation periods, in an institution or department of pathology recognized by the same council and the board of trustees as competent to provide a satisfactory training in the field of pathology. This period of special training preparation shall include the following:

(a) Graduate training for one year in the various phases of clinical pathology.

(b) Training and experience of not less than two years in a department of pathologic anatomy.

(c) Such training may be combined or in sequence.

3. A fifth year of training or practice in pathology.

D. Special qualifications:

1. The board may accept candidates without special training as outlined in Section C above provided that:

(a) The candidate shall have been for a period of five years of professional rank in a department of pathology in an approved medical school, or

(b) The candidate shall have been practicing pathology for ten years in a senior position in a hospital, having an adequate department of pathology, and approved by the Council on Medical Education and Hospitals of the American Medical Association.

Candidates with special qualifications, as outlined in Section D above, may be certified without examination, at the discretion of the board.

APPLICATION BLANK AND FEE

Application must be made on the special form which may be procured from the secretary and forwarded with other required credentials and the application fee. Applications cannot be given consideration by the board unless accompanied by the application fee.

The application or examination fee for candidates is \$35. If certified without examination \$10 of fee will be refunded. If the candidate fails in his examination he will be admitted to a second examination after one year, but not later than three years, without additional fee. After two reexaminations the applicant must file a new application and pay an additional fee before a fourth examination will be given.

The examination fee of \$35 has been arrived at after careful consideration, and is based on actual estimates of the expense of examination and administration. None of the board members receive any compensation for their services except actual expenses incurred.

If the applicant, for any reason, is deemed ineligible for examination by the board his fee will be returned; however, the application fee is not returnable after the candidate has officially been accepted for examination and notified to report for the same.

EXAMINATIONS

Written and oral examinations will be held at or near the time and place of national medical meetings at the discretion of the board. If a number of applications from any region of the country are received an examination in conjunction with a national medical meeting in that section will be arranged so that the financial outlay of the applicant in meeting the examinations will be as small as possible.

The examinations are to be based on the broad principles of pathology with emphasis on diagnosis and interpretation. The applicant may apply for certification in either pathologic anatomy or clinical pathology, or both.

DEFINITIONS

1. Pathologic anatomy is that branch of pathology which deals with the morphological aspects of disease, recognition being given that this definition covers two phases of pathology.

(a) The applied phase, with special attention to biopsy description and diagnosis.

(b) The academic phase of teaching and general morphological diagnosis.

2. Clinical pathology is that branch of pathology which deals with bacteriology, immunology, biochemistry, parasitology, hematology, and clinical microscopy, in relation to the diagnosis, prognosis, and treatment of clinical disease.

REEXAMINATIONS

In case the candidate fails in the qualifying examination he will be eligible for reexamination after one year has elapsed, but he must give written notice of his intention to appear for reexamination. Two reexaminations are allowed without an additional fee, providing they are taken within a three year period. The candidate who fails three times must file a new application and pay a second \$35 fee before he is eligible for further examination.

REVOCATION OF CERTIFICATES

Certificates issued by the American Board of Pathology are subject to the provisions of the Articles of Incorporation No. XI, Section 4. Any certificate issued by the Board of Trustees shall be issued subject to revocation in the event that:

(a) The physician or party so certified shall have made any misstatement or misrepresentation of a material fact in his application, or in any other communication to the board or its representatives, which misstatement or misrepresentation affected the eligibility of the physician or the party so certified.

(b) The issuance of such certificate has been made contrary to or in violation of any of the rules, laws, or regulations of this corporation.

(c) It is ascertained that the physician or party so certified is not eligible in fact to receive such certificate.

(d) The physician or party receiving such certificate shall prior to the issuance of such certificate or thereafter have been convicted by a court of competent jurisdiction of a felony or of any misdemeanor, which misdemeanor in the opinion of the Board of Trustees, shall involve moral turpitude.

(e) The physician or party receiving such certificate shall prior thereto, or thereafter, have his license to practice medicine revoked.

(f) The physician or party receiving such certificate shall be expelled from any of the societies or organizations making him eligible to this corporation as an applicant for such certificate.

All communications should be addressed to the secretary-treasurer.

AMERICAN BOARD OF PEDIATRICS, Inc.

BORDEN S. VEEDER, President, St. Louis.

C. ANDERSON ALDRICH, Secretary-Treasurer, 707 West Fullerton Avenue, Chicago.

HORTON CASPARIS, Nashville, Tenn.

FRANKLIN PAUL GENGEBACH, Denver.

CHARLES F. MCKHANN JR., Ann Arbor, Mich.

HAROLD COE STUART, Boston.

PHILIP VAN INGEN, New York.

ALFRED AUGUSTUS WALKER, Birmingham, Ala.

ORIGIN

The American Board of Pediatrics was established in June 1933 by joint action of the American Pediatric Society, the American Academy of Pediatrics and the Section on Pediatrics of the American Medical Association after consideration of the report of a committee on pediatrics as a special field of medical practice. The committee recommended that the certification plan adopted and in use in the fields of ophthalmology, otolaryngology, gynecology and obstetrics, and dermatology be adapted to pediatrics. Similar boards have been subsequently formed in all the other special fields.

In order to correlate the activities of the various qualifying boards there has been formed the Advisory Board on Medical Specialties, composed of representatives of all the qualifying boards, including the American Board of Pediatrics, as well as representatives of the Association of American Medical Colleges, the National Board of Medical Examiners, the Federation of State Medical Boards of the U. S. A. and the American Hospital Association.

Any method of certification in any specialty must be national in scope, must in its ultimate analysis be controlled by the men in each special field and must be independent of society membership or affiliation. The American Board of Pediatrics fulfills these three essentials: A uniform standard of competency is set up, the character of which is assured through the affiliation with the Advisory Board on Medical Specialties; the board is controlled by pediatricians, its membership being composed of three men appointed by each of the three national pediatric societies; the board is not a medical society, however, and certification is independent of society affiliation.

The American Board of Pediatrics was incorporated in the state of Delaware in November 1933 as a nonprofit organization.

FUNCTION

The functions of the board are outlined in the articles of incorporation as follows:

"To encourage the study, improve the practice and elevate the standards of pediatrics; and to grant and issue to physicians, duly licensed by law, certificates or other equivalent recognition of special knowledge in pediatrics."

The board has interpreted this to mean that its efforts to encourage and improve the practice of pediatrics shall be limited to its function of certification of competency in the specialty. Obviously other organizations are better able to further the general improvements in pediatrics.

The board specifically defines its activities as follows:

1. To establish standards by which the competency of men to practice pediatrics may be estimated.
2. To arrange, control and conduct examinations to test the qualifications of those desiring certification as pediatricians.
3. To grant certificates of qualification to those applicants who meet the standards successfully.

The board further feels that in carrying out these activities it is merely acting as the agent of the three societies which appointed its members and initiated the project.

No financial recompense of any kind is made to any member of this board except to cover actual traveling expenses to meetings and examinations. The \$30 application fee is fixed below that of any of the similar examining boards of other specialties. In the light of experience of the existing boards it may later be necessary to raise this fee to carry on the work of the board successfully.

CERTIFICATE—NOT A DEGREE

Certificates granted are in no sense degrees, nor do they purport to confer upon any person any legal qualification, privilege or license to practice pediatrics. Neither does the board intend in any way to limit the activities of any licensed physicians. It is merely attempting to standardize qualifications and to issue certificates to those who voluntarily comply with the requirements.

VALUE OF THE CERTIFICATE

It is anticipated that the certificate will become of value in that both the medical and lay public, including hospital directors, will soon utilize the certificate from this board as a means of discriminating between those who are well grounded as pediatricians and those who are not.

A certificate is required as one of the qualifications for new members of the American Academy of Pediatrics. The certificate of the American Board of Pediatrics is recognized by the Council on Medical Education of the American Medical Association. Holders of certificates are so designated in the directory of the American Medical Association.

A joint Directory of Specialists certified by the fifteen specialty boards was published in 1940 by the Advisory Board for Medical Specialties.

Lists of those holding certificates from this board are published in this Directory of Medical Specialists and additional lists of new licentiates are published in the Journal of Pediatrics and the American Journal of Diseases of Children. The American Medical Directory indicates diplomates of this and other boards by means of abbreviations and symbols (A.B.I.) appearing in the biographic records.

This board, in cooperation with the Council on Medical Education and Hospitals of the American Medical Association, is conducting a survey of institutions providing acceptable residencies and internships in pediatrics.

APPLICANTS FOR CERTIFICATES

Requirements for Applicants.—Each applicant for a certificate must establish in a manner satisfactory to the board that he is of high ethical and professional standing, is a graduate of a medical school which is satisfactory to the board, and has received adequate training in pediatrics as a specialty in addition to passing the examination given by this board.

Applicants must be citizens of the United States, of its dependencies, or of Canada.

Applicants will be divided into two classes, according to the length of time they have been engaged in the specialty.

Following is the classification of applicants for certification. The changes are based upon the experience gained from examination and upon the general requirements as adopted by the Advisory Board of Medical Specialties and the Council on Medical Education and Hospitals of the American Medical Association.

All applicants must take the examinations.

Group I.—Physicians who have specialized in pediatrics for ten years or more. After July 1, 1943, Group I will be abolished.

The minimum requirements for *Group II* are as follows: Graduate of a Class A medical school.

One year's intern service in a recognized hospital.

Two years' service in a pediatric center.*

An additional term of two years of specialized study and/or practice.

The board defines service in a pediatric center as full time devoted to rounded experience in an acceptable hospital or a graduate course, which includes ward and outpatient service and both therapeutic and preventive pediatrics. The time served in pediatric centers need not be continuous or spent in the same institution. In the case of a post-graduate course an academic year will meet the requirement of one year's work.

The application fee is \$30 and must be remitted with the application. Refund will be made only if the applicant is refused examination. The applicant who has failed in an examination will not be required to pay a second fee if he takes another examination after the lapse of two years.

Application must be made on special blanks which may be secured from the secretary. These must be sent to the secretary at least four months before the date at which the candidate expects to take the examinations.

Letters from two competent pediatricians recommending each applicant must be sent to the secretary of the board. These letters are not to accompany the application, but should be sent directly to the secretary. No member of the board may recommend any applicant.

INFORMATION CONCERNING EXAMINATIONS

Examinations will be held at or near the time and place of meetings of the American Medical Association and of the American Academy of Pediatrics, or at other times and places at the discretion of the board, depending on the number of applicants from any region of the country. It is proposed to arrange examinations in different cities so that as little financial burden as possible will be placed upon the applicants in meeting the examiners.

The purpose of these examinations is to determine the applicant's competency to practice pediatrics. This board feels that the best impression of an applicant's ability can be obtained by oral examination although written ones may be substituted at times. However, at the present time this board is also giving a written examination at least six weeks preceding the oral examination. This written examination is given locally under a monitor. It is not proposed at the present time to require the applicant to send in case reports. The board feels that growth and development are fundamental parts of pediatric training.†

A list of papers or books published must be sent with the application blank.

It should be emphasized that competency in the practice rather than in the theory of pediatrics is required.

Communications should be addressed to the secretary.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY, Inc.

HISTORY AND STATEMENT OF PRINCIPLES

The American Board of Psychiatry and Neurology was founded in 1934 following conferences of committees appointed by the American Psychiatric Association, the American Neurological Association, and the Section on Nervous and Mental Diseases of the American Medical Association. This action was taken in response to a widespread desire among specialists in psychiatry and neurology for some means of distinguishing the fully qualified specialist from the would-be specialist of inferior training and inadequate experience. That this desire is by no means limited to those who practice psychiatry and neurology is indicated by the formation of corresponding boards

* A maximum of six months of this time may be spent in full time continuous work in a recognized hospital.

† The three volumes on Growth and Development of the White House Conference contain this material, Century Company, publishers.

covering internal medicine, surgery, and the major specialties. The success of this method of distinguishing the specialists is indicated by the increasing number of candidates taking the examinations, and by the listing accorded in the American Medical Directory to those specialists holding the certificates of the various boards.

CONSTITUTION AND ACTIVITIES

The American Board of Psychiatry and Neurology is composed of twelve members, four each from the American Neurological Association and from the American Psychiatric Association and two neurologists and two psychiatrists elected by the Section on Nervous and Mental Diseases of the American Medical Association. Annual elections to fill the places of members whose terms have expired take place in each of the nominating associations with the understanding that neurology and psychiatry are always equally represented on the board. The board holds annual meetings in December of each year for the transaction of whatever business may come before it and also holds special meetings for the purpose of examining candidates and of passing upon the qualifications of those seeking the certificate without examination.

FUNCTIONS

(a) To determine the competence of specialists in psychiatry and neurology.

(b) To arrange, control and conduct investigations and examinations to test the qualifications of voluntary candidates for certificates issued by the board.

(c) To grant and issue certificates or other recognition of special knowledge in the field of psychiatry and neurology to successful voluntary applicants therefor.

(d) To serve the public, physicians, hospitals and medical schools by preparing lists of practitioners who shall have been certified by the board.

(e) To consider and advise as to any course of study and technical training, and to diffuse any information calculated to promote and ensure the fitness of persons desirous of qualifying for a certificate of qualification to be issued thereby.

INFORMATION FOR APPLICANTS

EXCERPTS FROM ARTICLE VII OF THE BY-LAWS

SECTION 1. *Application for Certificates.* Application for certificates shall be considered by the secretary only when made formally on the official application blank in such form as may be adopted from time to time by the board of directors and when accompanied by an application fee in such amount as may be fixed from time to time by the board of directors.

SECTION 2. *Form of Certificates.* There shall be separate certification in psychiatry and in neurology and two certifications or a combined certification for those qualified in both fields. The certificates shall be in such form as is approved by the board of directors.

SECTION 3. *Requirements for Applicants.* Each applicant for a certificate must establish that—

(a) He is a physician duly licensed by law to practice medicine.

(b) He is of satisfactory ethical and professional standing.

(c) He is now a member of the American Medical Association, or a member of such medical societies as are recognized for purposes of certification by the Council on Medical Education and Hospitals of the American Medical Association. Exceptions to the foregoing may be made at the discretion of the board for good and sufficient reasons.

(d) He has received adequate training in psychiatry or neurology, or both, as a specialty.

SECTION 4. No candidate is eligible for examination by the board until he has completed at least five years of special training and experience in neurology or psychiatry for a single certificate, or at least six years of training and experience for certification in both neurology and psychiatry.

CLASSES OF APPLICANTS AND FEES

Applicants may request certification in psychiatry, or in neurology, or in both psychiatry and neurology.

Limitation of practice to the specialty of psychiatry and/or neurology need not be complete provided a candidate both by his previous training, experience and standing, and by examination, can prove his competency to practice that specialty.

However, in case a physician has already been certified by one of the other boards as a specialist in another field, he will not be considered for certification in psychiatry and/or neurology except under special circumstances.

Class I

Physicians who graduated from medical school in 1919 or before and who have carried on specialized practice in neurology and/or psychiatry for at least fifteen years are to be

considered on their professional record and passed, if satisfactory to the Board, or further evidence of qualification or examination may be required.

A candidate in Class I who has received certification in either psychiatry or neurology may apply within three years for certification in the other field without additional fee. After three years such application shall be considered as a new application with corresponding fees.

When certification in Class I has been refused, the candidate may file application for reconsideration within three years without additional fee. After three years such application for reconsideration shall be considered as a new application with corresponding fees.

Class II

Physicians who graduated from medical school up to and including 1929 and who have practiced the specialty of psychiatry and/or neurology for at least five years will be required to pass an examination in psychiatry or neurology, or both.

Class III

Physicians who graduated after 1929, up to and including 1934, will be required to pass an examination to satisfy the board that they have adequate knowledge of all subjects specified in the by-laws for candidates graduating after 1934. Their previous training and experience must be acceptable to the board.

Class IV

Candidates graduating from medical school after 1934 shall fulfil the preceding general requirements as given in Section 3 of Article VII and the following special requirements:

PROFESSIONAL EDUCATION

(1) Graduation from a medical school approved by the Council on Medical Education and Hospitals of the American Medical Association.

(2) Completion of a general internship of not less than one year in a hospital approved by the same Council.

SPECIAL TRAINING

(These requirements are to be placed in force as soon as practicable after Jan. 1, 1944. In the meantime a syllabus covering the knowledge required of the candidate has been prepared and is available to those who request it.)

Admission to the examination for certification in neurology or psychiatry requires a total experience of not less than five years. This period shall include the following:

1. A period of study, after the general internship, of not less than three full years in institutes, hospitals, clinics, dispensaries, laboratories, and other institutions recognized by the Council of the American Medical Association and approved by the American Board of Psychiatry and Neurology as competent to provide a satisfactory training in psychiatry and/or neurology.

(a) As subject matter,

Neuro-anatomy
Neurophysiology
Neuropathology
Clinical neurology

Psychobiology
Psychopathology
Neurodiagnosis
Clinical psychiatry

and other basic medical sciences, which, in the opinion of this board, are necessary to the proper understanding and treatment of psychiatric and/or neurologic disorders.

2. An additional period of not less than two years of practice in psychiatry and/or neurology.

3. Candidates wishing to be admitted to the examinations for certification in both fields must have had a minimum of six years of experience in both fields.

PAYMENT OF FEES

The candidate on filing his application shall accompany it with an application fee of \$25. When notified by the secretary that he is eligible for examination he shall send the examination fee of \$25 to the secretary at least two weeks before the date of the examination. The certification fee of \$25 is payable upon notification by the board that certification has been awarded the candidate in Class I on his record. No fees will be returned.

The same examination is given whether a candidate applies for certification in psychiatry, or in neurology, or in both psychiatry and neurology. The board requires some proficiency in neurology on the part of those it certifies in psychiatry and vice versa, but judges the candidate in accordance with the certificate he seeks.

Should a candidate receive certification in either psychiatry or neurology, he may apply within three years for partial examination for the certificate in the complementary subject, upon payment of a complementary examination fee of \$10. After three years, the second application shall be considered a new application, with corresponding \$25 fees.

EXAMINATIONS

Date and places of examination are set by the board at its discretion and are announced in *The Journal of the American Medical Association*, in the *American Journal of Psychiatry*, in the *Journal of Nervous and Mental Disease*, and in the *Archives of Neurology and Psychiatry*.

The examinations are designed to test the ability of the candidates to meet the situations in which they might at any time be called upon as specialists to assume responsibility. They will be of such a type that no adequately trained individual will fail, yet they will be sufficiently searching so that the specialist-in-fact will be separated from the specialist-in-name. Each candidate is required to identify and to discuss the function of the more important anatomic structures in the brain and spinal cord, to discuss gross and microscopic pathologic specimens and to interpret roentgenograms dealing with neurologic disorders. He is examined orally on the subjects of psychobiology and psychopathology. These examinations in the preclinical subjects usually last about two hours. Each candidate examines two patients with neurologic disorders and two with psychiatric disorders, and discusses with the examiners the various problems involved. One hour, on the average, is allotted to each of these four clinical examinations. The manner of examining both neurologic and psychiatric patients and the reasoning and deductions therefrom constitute the most important part of the examination. Some acquaintance with the history of psychiatry and neurology, with the body of doctrine, and with the recent advances, is presupposed.

REEXAMINATIONS

A candidate who has failed in one examination is eligible to reexamination in the whole subject, within three years, on payment of a reexamination fee of \$10. A candidate who has failed in one examination and who does not apply for reexamination within three years or a person who has applied within that time but who has failed a second time will be considered a new applicant, with corresponding \$25 fees. The \$10 reexamination fee also applies to candidates conditioned in one or more subjects at any time within three years of the first examination, and is payable before each reexamination.

HANDLING OF APPLICATIONS

An application, in order to be considered at any meeting, must be in the hands of the secretary of the board not less than seventy days before the date of such meeting.

The secretary of the board on receipt of an application shall forthwith make inquiries from those to whom the candidate refers and from such other persons as the secretary may deem desirable and shall verify the candidate's record from the biographical records of the American Medical Association, after which he shall forward the application to the committee on credentials. This committee shall consider the application and other information available and notify the secretary whether the application is accepted. The certification of a candidate in either psychiatry or neurology, or both, shall be approved by a majority of the members of the entire Board at any meeting held for such certification.

PLEDGE

Each candidate is required to sign the following pledge:

"I hereby make application to the American Board of Psychiatry and Neurology, Incorporated, for the issuance to me of a certificate of qualification as a specialist in (a) Psychiatry; (b) Neurology; (c) Psychiatry and Neurology (check the one desired) and for examination relative thereto, all in accordance with and subject to its rules and regulations. Upon the issuance of the certificate I agree to and do become bound by the by-laws of the American Board of Psychiatry and Neurology, Inc., insofar as applicable.

"I agree to disqualification from examination or from the issuance of a certificate of qualification or to forfeiture and redelivery of such certificate of qualification in the event that any of the rules governing such examination are violated by me or for any one of the reasons set forth in the by-laws. I agree to hold said American Board of Psychiatry and Neurology, Inc., its members, examiners, officers and agents, free from any damage or claim for damage or complaint by reason of any action they, or any of them, may take in connection with this application, such examination, the grade or grades given with respect to any examination, and/or the failure of said corporation to issue to me such certificate of qualification."

RULES AND REGULATIONS

(ART. VII, SEC. 5, OF THE BY-LAWS)

The board of directors, from time to time, by resolution adopted by the affirmative vote of a majority then in office, may adopt, amend and repeal rules and regulations respecting

requirements of applicants, the nature and extent of examinations and investigations and issuance of certificates.

REVOCATION OF CERTIFICATES
(ART. VII, SEC. 6, OF THE BY-LAWS)

All certificates issued by the corporation shall be issued subject to the provisions of the certificate of incorporation and of the by-laws of the American Board of Psychiatry and Neurology, Inc. Each such certificate shall be subject to revocation in the event that:

(a) The issuance of such certificate or its receipt by the physician shall have been contrary to or in violation of any of the provisions of the corporation's certificate of incorporation or by-laws; or

(b) The physician so certified shall not have been eligible in fact to receive such certificate, irrespective of whether or not the facts constituting him so ineligible were known to any or all of the directors of the corporation or could have been ascertained by any or all of the directors of the corporation at the time of the issuance of such certificate; or

(c) The physician so certified shall have made any deliberate misstatement of fact in his application for such certificate or in any other statement or representation to the corporation, its directors, representatives or agents; or

(d) The physician so certified shall have been convicted by a court of competent jurisdiction of a felony or of any misdemeanor involving, in the opinion of the board of directors of the corporation, moral turpitude in connection with his practice of medicine; or

(e) The physician so certified shall have had his license to practice medicine revoked or shall have been disciplined or censured as a physician by any court or other body having proper jurisdiction and authority.

FORM OF CERTIFICATE

The secretary shall have prepared subject to the approval of the board members a form of certificate containing the following wording:

THE AMERICAN BOARD OF PSYCHIATRY AND
NEUROLOGY, INC.

This is to certify that.....has satisfied the requirements of the board and is hereby certified as qualified to practice the specialty of Psychiatry and/or Neurology.

(Signed) President.....
Vice President.....
Secretary

Communications should be addressed to the secretary.

BERNARD P. WIDMANN, Philadelphia.

HISTORY AND AUTHORITY FOR ORGANIZATION

The medical profession has long felt that there should be a standard of minimal requirements for the practice of any specialty in medicine in order to protect the public, the profession in general, and the specialists themselves. Some of the states have attempted by statute to prescribe such requirements in certain branches. Unless a better method of regulation were found, the other states would be likely to enact similar laws. The result would be forty-eight different standards for each of the many medical specialties. Obviously, a more practicable solution would be for each special group to put its own house in order and place its mark of approval on those qualified to practice as specialists in that particular field. Accordingly, in 1932, five nation-wide radiologic organizations, the Section on Radiology of the American Medical Association, the American Roentgen Ray Society, the Radiological Society of North America, the American College of Radiology, and the American Radium Society, each appointed a committee of three members to confer and investigate the feasibility of establishing a quali-

ying board. The following men were appointed by these five organizations: Drs. G. W. Holmes, J. W. Pierson, E. L. Jenkinson, W. E. Chamberlain, E. C. Ernst, W. F. Manges, L. K. Sante, L. C. Kinney, A. C. Christie, Albert Soiland, W. W. Wasson, Henry Schmitz, Lester Hollander, Rollin H. Stevens and B. R. Kirklin.

This combined committee met at Milwaukee in 1933, during the meeting of the American Medical Association, agreed unanimously that such a board should be established and so reported to the respective organizations. Each of the organizations approved the report, appointed three representatives, and empowered them to proceed to the formation of a national radiologic board. The members of the board thus chosen were: Drs. W. F. Manges, L. R. Sante and B. R. Kirklin, representing the American Roentgen Ray Society; Drs. A. C. Christie, E. C. Ernst and E. L. Jenkinson (succeeding Dr. Byron H. Jackson, originally appointed) representing the American College of Radiology; Drs. R. H. Stevens, Henry Schmitz and H. K. Pancoast, representing the American Radium Society; Drs. L. J. Menville, M. C. Sosman and Albert Soiland, representing the Radiological Society of North America, and Drs. L. C. Kinney, J. W. Pierson and G. W. Holmes, representing the Section on Radiology of the American Medical Association.

The board was incorporated, organized and held its first meeting in Washington, D. C., in May 1934; at that time the by-laws were adopted and provision was made by resolution for its proper function. The officers of the board elected at this meeting were:

Dr. H. K. Pancoast, President.
Dr. A. C. Christie, Vice President
Dr. B. R. Kirklin, Secretary-Treasurer.

This move put into action the determined effort on the part of these five national organizations to improve the standards of the practice of radiology. It expects to accomplish this by various activities, such as the investigation and encouragement of facilities for graduate extension study and active clinical assistantships for men desiring to specialize in radiology; it will endeavor by regular examinations to determine the competence of specialists in radiology who apply for the certificate.

During 1935 the American Board of Radiology was accepted for membership in the Advisory Board for Medical Specialties and was also approved by the Council on Medical Education and Hospitals of the American Medical Association. Hereafter the list of Diplomates of the Board will take the place of the Council's list of approved radiologists, and the latter list will be discontinued.

PURPOSES

First: To encourage the study and promote and regulate the practice of radiology.

Second: To elevate the standards and advance the cause of radiology by encouraging its study and improving its practice.

Third: To determine the competence of specialists in radiology; to arrange, control and conduct investigations and examinations; and to test the qualifications of voluntary candidates for certificates to be issued by the board.

Fourth: To serve the public, physicians, hospitals and medical schools by preparing lists of practitioners who shall have been certified by the board.

VALUE OF CERTIFICATE

The national radiologic organizations which have participated in the formation of the board and are sponsoring its activities, as well as other organizations, attach considerable importance to its certificate. It is expected that both the medical and the lay public, including hospital directors, will soon come to utilize the certificate from this board as a means of discriminating between those who are well grounded as specialists in radiology and those who are not.

To this end lists of those holding certificates from this board will be published and issued from time to time by the board. Similar lists will be published by the *American Journal of Roentgenology and Radium Therapy, Radiology, and The Journal of the American Medical Association*. The Directory of the American Medical Association will indicate by a numerical symbol in the biographic data of those whose names are eligible to appear on these lists that they are diplomates of this board.

For emphasis it is repeated that the board does not intend in any way to interfere with or limit the professional activities of any duly licensed physician, but it does aim toward standardized qualifications for those who claim to be specialists in radiology.

CERTIFICATES

A certificate will be issued to each candidate who meets the requirements of the board, to the effect that the holder of the certificate has had adequate training in radiology and has successfully fulfilled the requirements of the board.

A certificate granted by this board does not of itself confer, or purport to confer, any degree, or legal qualifications, privileges, or license to practice radiology. Certificates of the board shall be issued upon one of two forms:

1. A certificate to the effect that the applicant has been found qualified to practice radiology in all its branches.

2. A certificate to the effect that the applicant has been found qualified to practice radiology in one or more of the following special fields: (a) roentgenology; (b) diagnostic roentgenology; (c) therapeutic radiology.

DEFINITIONS

For the purposes of this board, the following definitions are adopted:

1. Radiology is that branch of medicine which deals with the diagnostic and therapeutic application of radiant energy including roentgen rays and radium.

2. Roentgenology is that branch of radiology which deals with diagnostic and therapeutic application of roentgen rays.

3. Diagnostic roentgenology is that branch of radiology which deals with the diagnostic application of roentgen rays.

4. Therapeutic radiology is that branch of radiology which deals with the therapeutic application of roentgen rays and radium.

GENERAL REQUIREMENTS

Each applicant for admission to the examination shall be required to present evidence that he has met the following standards:

(A) General Qualifications.*

(1) Satisfactory moral and ethical standing in the profession.

(2) A license to practice medicine.

(3) Membership in the American Medical Association, or, by courtesy, membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association.

(4) That the applicant holds himself out to be a specialist in radiology or one of its branches as defined under definitions, and that he uses roentgen rays or roentgen rays and radium either personally or under his direct supervision in a substantial portion of his practice.

(B) Professional Education.*

(1) Graduation from a medical school of the United States or Canada, recognized by the Council on Medical Education and Hospitals of the American Medical Association.

(2) Completion of an internship of not less than one year in a hospital approved by the same council.

(3) Three years' training in radiology or sufficient experience in lieu thereof.

(C) Special Training.* (To be effective Jan. 1, 1942.)

(1) A period of study after the internship of not less than three calendar years in an institution or radiologic department recognized by the same council and the board as competent to provide a satisfactory training in the field of radiology.

(2) This period of specialized preparation shall include:

(a) Graduate training in pathologic anatomy, radiophysics, and radiobiology.

(b) An active experience of not less than twenty-four months in a radiologic department recognized by the board and the council as capable of providing satisfactory training.

(c) Examination in the basic sciences of radiology as well as in the clinical aspects thereof.

APPLICATIONS

The board desires to appraise the candidate's educational opportunities (premedical, medical and radiologic), the ability of his instructors, his hospital and teaching positions, his original investigations, his contributions to radiologic literature, his membership in medical societies, and his local and general reputation.

For this purpose, application must be made on a special blank which may be obtained from the secretary. No application will be considered unless made on the regular application blank. This application shall be forwarded with the required data, two unmounted photographs, and the fee of \$35, at least two months before the date of the examination.

FEE

A fee of \$35 must accompany each application blank. This fee will not be returned and no application will be considered until the fee is received. This fee has been carefully computed

*NOTE: In case of an applicant whose training has been received outside of the United States and Canada, the credentials must be satisfactory to the Advisory Board for Medical Specialties.

and is used entirely for administrative purposes. Members of the board and special examiners do not receive any compensation except for actual expenses connected with holding the examinations. As the number of candidates decreases, it may become necessary to raise the fee.

Checks should be made payable to the American Board of Radiology.

EXAMINATIONS

Each year the board will hold an examination in conjunction with the annual meeting of the American Medical Association, and, when sufficient applications are on file, a second examination will be held in conjunction with the annual meeting of the American Roentgen Ray Society and/or the Radiological Society of North America.

For the present, examinations consist of practical and oral examinations, although written examinations may be added later. The examinations are designed to test the candidate's fitness to practice radiology or one of its branches as a specialty. The board will endeavor to adapt this examination to the candidate's experience and years of practice. It will try especially to ascertain the breadth of his clinical experience, his knowledge of the basic sciences of radiology, and likewise his knowledge of the recent literature on radiology, and his general qualifications as a specialist in this branch of medicine.

The examination consists of tests in film interpretation and an oral examination in pathology, physiology, radiophysics and radiobiology, as well as the clinical applications of roentgen rays and radium. The applicant is also examined in "professional adaptability," in an attempt to ascertain his attitude toward his fellow practitioners and his patients.

Whenever an applicant fails to pass the examination, the board, if requested, will make suggestions as to suitable courses of instruction for the purpose of overcoming his deficiencies.

REEXAMINATIONS

If the candidate fails in an examination he will be admitted to a second examination after one year has elapsed but not more than three years. He must give sixty days' notice of his intention to appear for reexamination and pay an additional fee of \$15. If a candidate who has failed does not appear for reexamination before the expiration of three years, he will be required to make a new application and pay an additional fee of \$35.

A candidate having failed twice must file a new application and pay an additional fee of \$35.

FINAL ACTION OF THE BOARD

The final action of the board is based on the applicant's professional record, training, and attainments in the field of radiology, as well as on the results of his examination. Any radiologist who is practicing radiology honorably and efficiently should have no difficulty in obtaining a certificate. This board has been organized, not to prevent qualified radiologists from obtaining certificates, but to assist them in becoming recognized in their communities as men competent to practice in the special field of radiology.

REVOCATION OF CERTIFICATES

Certificates issued by this board are subject to the provisions of the Articles of Incorporation and the By-Laws. According to Article IX, Section 4, of the By-Laws "Any certificate issued by the Board of Trustees shall be subject to revocation in the event that:

(a) The issuance of such certificate or its receipt by the physician so certified shall have been contrary to or in violation of any provision of the Certificate of Incorporation of this the American Board of Radiology or of these by-laws; or

(b) The physician or party so certified shall not have been eligible in fact to receive such certificate; or

(c) The physician or party so certified shall have made any misstatement of fact in his application or in any other communication to the board or its representatives; or

(d) The physician or party so certified shall have been convicted by a court of competent jurisdiction of a felony or of any misdemeanor involving, in the opinion of the Board of Trustees, moral turpitude; or

(e) If the physician or party so certified shall have had his license to practice medicine revoked or shall have been expelled from one of the societies or organizations which is represented by this corporation through eligibility of such society or organization to nominate and appoint members of this corporation."

Communications should be addressed to the secretary.

AMERICAN BOARD OF SURGERY, Inc.

ALLEN O. WHIPPLE, Chairman, New York.

ERWIN R. SCHMIDT, Madison, Wis.

PHILEMON E. TRUESDALE, Fall River, Mass.

HISTORY

The organization of the American Board of Surgery was completed on Jan. 9, 1937. A plan for this organization had been carefully studied by a general committee representative of certain general and sectional surgical societies called together through the initiative of the American Surgical Association. As a result of the deliberations of this general committee a tentative plan of organization was adopted. This plan was reported to the cooperating surgical societies and was approved with the understanding that the board, when organized, would have the power to change or modify the proposed plan as it saw fit. This board has been created in accordance with the action of the Advisory Board for Medical Specialties as approved by the Council on Medical Education and Hospitals of the American Medical Association, which has named certain specialty fields as being suitable to be represented by such boards. These boards have the twofold purpose of certifying those found to be qualified after meeting reasonable requirements, and of improving existing opportunities for the training of specialists within the field concerned. This is to be done for the protection of the public and the good of the specialty.

PERSONNEL

* The cooperating surgical societies selected jointly to form the board appointed their representatives as follows:

The American Surgical Association.....	3
The Surgical Section of the A. M. A.....	3
The American College of Surgeons.....	3
The Southern Surgical Association.....	1
The Western Surgical Association.....	1
The Pacific Coast Surgical Association.....	1
The New England Surgical Society.....	1

13

The term of membership is for six years. Each cooperating association has the appointing power of its representatives subject to the approval of the board.

PURPOSES

(a) To conduct examinations of satisfactory candidates who seek qualification by the Board.

(b) To issue certificates of qualification to all those meeting the board's requirements.

(c) To improve the opportunities for the training of the surgeon.

REQUIREMENTS

(A) GENERAL QUALIFICATIONS

1. Moral and ethical standing in the profession satisfactory to the board.

The board, believing that the practice of "fee splitting" is pernicious, leading as it does to a traffic in human life, will reserve the right to inquire particularly into any candidate's practice in regard to this question.

2. Membership in the American Medical Association or, by courtesy, membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the A. M. A. Except as here provided, membership in other societies shall not be required.

3. Those who have limited their activities to the practice of surgery.

4. In exceptional instances the board may, in its discretion, accept for examination candidates who have met all preliminary requirements and have been in practice from six to sixteen years but whose formal training does not comply with the full requirements to be exacted in the future.

* The first three of these associations being national in scope, were allotted three representatives each, the remaining associations, etc.

The board recognizes two groups of candidates who may be eligible for certification.

(A) The Founders Group—those who have already amply demonstrated their fitness as trained specialists in surgery. Application for membership in this group will be open until January 9, 1940. Those who receive the board's approval will be accepted for membership without examination from the following:

1. Those who from the time of the board's organization, January 9, 1937, hold the position of Professor or Associate Professor of Surgery in the approved medical schools of the United States or Canada.

2. Those who for fifteen years prior to the board's organization have limited their practice to surgery and have met the general qualifications required.

3. Such members of the cooperating societies represented on the board, in good standing January 9, 1937, who may be invited to membership in this group.

This group was closed January 1, 1940; no further applications received.

(B) Qualified by examination—

In addition to the general qualifications the requirements for this group shall be as follows:

(B) PROFESSIONAL STANDING

1. Graduation from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the A. M. A., or graduation from an approved foreign school.

2. Completion of an internship of not less than one year in a hospital approved by the same Council, or its equivalent in the opinion of the board. This internship may be rotating or one devoted to a single branch of medicine as, for example, surgery, medicine, pathology, etc.

(C) SPECIAL TRAINING

After the completion of the year's internship there shall be a period of special training in surgery of not less than five years. During this period one's entire time must be devoted to surgical training supplemented by sufficient experience in the basic sciences to comply with the provisions of Paragraph 2. Such training may be taken in a recognized graduate school of medicine, as resident in surgery in an acceptable hospital, or under a sponsorship accredited by the American Board of Surgery for such training.† By the latter statement is meant that one may secure the necessary training as an assistant to an accredited surgeon, provided suitable facilities for the education of the candidate are offered. It is understood that the board will accept a combination of training as outlined above.

(For example, one may take a graduate course in an acceptable graduate school for one year, a residency of two years, and an assistantship of two years.)

This period of special training shall be of such character that the relation of the basic sciences of anatomy, physiology, pathology, bacteriology and biochemistry is emphasized. Knowledge of these sciences as applied to clinical surgery will be required in the examination.

Adequate operative experience in which the candidate has assumed the whole responsibility will be required.

The above requirements, especially those referring to surgical training, are subject to change from time to time as the existing opportunities for training in this field of specialization may be broadened.

EXAMINATIONS

The qualifying examination will be divided into Part I (written) and Part II (clinical, bedside and laboratory). In both of these parts a knowledge of the practical application of the sciences fundamental to surgery will be required as previously stated.

PART I

This may be given simultaneously in as many centers as the board may determine suitable for the purpose. A candidate to be eligible for Part I must meet all requirements for Group B candidates. A card of admission to this part of the examination will be forwarded to the candidate from the secretary's office, certifying that these requirements have been met, as well as due notice as to the time and place of the examination.

The examination in Part I shall cover a one day period. There shall be two sessions of three hours each. This written examination shall concern itself primarily with general surgical problems and in addition the application of the basic sciences of surgery to these problems.

† The board makes no attempt to classify hospital residencies, usually accepting those approved by the American College of Surgeons and the Council on Medical Education and Hospitals of the American Medical Association.

PART II

In order to be eligible for Part II a candidate must have successfully passed Part I in addition to having met the necessary preliminary requirements and having presented definite evidence of an adequate training in operative surgery satisfactory to the board.

This part of the examination shall be oral and practical and cover a one-day period, the schedule being arranged somewhat as follows:

8-9 A. M.—REGISTRATION

9 A. M.—12 Noon.—Clinical Surgery (diagnosis and management and the application of physiology, biochemistry and bacteriology, as the case being examined on may offer an opportunity for doing so. X-ray plate interpretation will also be included).

2-5 P. M.—Applied anatomy and surgical pathology.

The examinations in Part II are conducted in certain centers of the country selected by the board. It is the board's desire to arrange these centers so as to geographically meet the needs of the candidates, provided suitable examination facilities can be met. The examination in this part will be conducted by members of the board living in the region of the country in which they are held, together with selected members of the Founders Group resident in the center chosen.

GRADES

A candidate must receive a passing average for each part to be entitled to the board's certificate. No candidate shall pass a part who does not receive a grade of 60% or over in each subject of such a part. An average grade of 75% shall be considered as passing in each part. The following values have been assigned to Part II on the basis of the total of 100%; clinical surgery 50%, anatomy 30%, pathology 20%.

A candidate who fails in his examination in Part I shall have his papers reviewed by the examination committee.

REEXAMINATIONS

Candidates may be reexamined as often as they desire provided one year shall elapse between examinations, except that the board may, for good and sufficient reason, deny a candidate the privilege of reexamination.

Candidates shall be required to pay the same fees for Parts I and II at each reexamination in these parts.

FEES

The fee for Group A, Founders Group, shall be \$25.

The fee for Group B shall be \$75, payable as follows: \$5 registration fee, which shall be returned if the candidate is not accepted for examination; \$20 for Part I; and \$50 for Part II.

This board is a non-profit organization. All fees will be used, after a reasonable amount is set aside for necessary expenses in maintaining its office, conducting examinations, etc., to aid in improving existing opportunities for the training of the surgeon.

CERTIFICATE

A certificate attesting to a candidate's qualification in surgery after meeting the requirements will be issued by the board, having been signed by its officers.

REVOCATION OF CERTIFICATE

Any certificate issued by the board shall be subject to revocation by the board at any time in case it shall determine in its sole judgment that a candidate, who has received a certificate, either was not properly qualified to receive it or has become disqualified since its receipt.

Proper forms for making application, and other information, will be furnished by the secretary-treasurer.

AMERICAN BOARD OF UROLOGY, Inc.

HERMAN L. KRETSCHMER, President, Chicago.

CLARENCE G. BANDLER, Vice President, New York.

GILBERT J. THOMAS, Secretary-Treasurer, 1009 Nicollet Avenue, Minneapolis.

NATHANIEL P. RATHBUN, Brooklyn.

GEORGE GILBERT SMITH, Brookline, Mass.

CHARLES C. HIGGINS, Cleveland.

HENRY G. BUGBEE, New York.

ALFRED I. FOLSON, Dallas, Texas.

THOMAS LEON HOWARD, Denver.

ORGANIZATION

At the annual meeting of the American Association of Genito-Urinary Surgeons held at Niagara Falls, Ont., Canada, May 26-28, 1932, Dr. William F. Braasch called attention to the various qualification boards which had been established, or were

This period of specialized preparation should include:

- (a) graduate training in anatomy, physiology, pathology, and the other basic medical sciences which are necessary to the proper understanding of the disorders and treatment involved in the specialty of Urology.
- (b) an active experience of not less than eighteen months in hospital clinics, dispensaries and diagnostic laboratories recognized by the Council on Medical Education and Hospitals of the American Medical Association as competent in the diagnosis and treatment of urologic conditions.

(c) examinations in the medical sciences basic to the specialty of Urology, as well as in the clinical, laboratory and public health aspects.

2. An additional period of not less than two years in the private practice of urology in the city from which he makes application.

These special requirements conform with the suggestions made by the Council on Medical Education and Hospitals of the American Medical Association.

C. Make application to the American Board of Urology, Inc., whose duty it shall be to investigate the applicant's credentials and make a survey of his character;

D. Assure the board that he is engaged in the practice of urology and that he intends to continue to be so engaged;

E. Membership in the American Medical Association, or comparable national medical society, is recommended.

FEE

The examination fee will be \$75. Fifteen dollars must accompany the application. Sixty dollars is to be paid when the applicant is accepted as a candidate for certification. This is the total expense to the candidate. If a candidate fails in his examination, he will be permitted a second examination after one year, or within three years, without additional fee, but he must give sixty days' notice of his intention to appear for reexamination. After an applicant has failed twice, he must file a new application blank accompanied by a second fee. If an applicant is lacking in any of the requirements as stated above, he will be considered ineligible for examination and classification and his fee will be returned. In no other instance, however, will a refund of the examination fee be possible.

REQUIREMENTS FOR CERTIFICATION

According to the By-laws of the American Board of Urology, Inc., applications received from applicants for certification shall be examined by the Credentials Committee and reviewed by the board. When additional data are required to complete the application, these will be requested by the secretary's office.

The requirements for certification include: personal appearance before the board; preparation of fifty case reports of major urological cases under the candidate's own supervision which must contain all items essential for diagnosis, therapy, prognosis, results of treatment, etc.; oral and clinical examinations; written examinations.

In specific instances, the board may waive any part of these requirements, with the exception of the item of personal appearance.

Each candidate will receive a notice of the time and place of the examinations, and an appointment for his personal appearance before the board.

EXAMINATIONS, WHERE HELD, AND REPORTS OF CASE HISTORIES

The board will hold one examination a year. This will be held at a time or place that the board may select or deem expedient.

1. The *written examinations* are designed to test the candidate's preparation in, and his knowledge of, the whole subject of urology, including the fundamental subjects: pathology, anatomy, physiology, embryology, bacteriology, physiological chemistry and endocrinology. The examination in pathology will consist of the identification of gross specimens and of sections of tissue observed through the microscope. The examination in anatomy, physiology, embryology, bacteriology, physiological chemistry, and endocrinology will be a test of the candidate's working knowledge of these subjects as they are related to the practice of urology.

2. The oral and clinical examinations will consist of discussions of common urologic conditions. The subjects forming the basis of the oral examinations are urography, diseases of the genital organs, including the prostate, diseases of the urinary bladder, and diseases of the ureters and kidneys. The oral examination may deal directly with the reports of case histories which the candidate has submitted. This examination will ascertain the candidate's familiarity with recent urologic literature, the breadth of his clinical experience, and his general qualifications as a specialist in urology. The applicant also will be examined in "professional adaptability" in an attempt to ascertain his attitude toward his fellow practitioners and his patients.

3. The *reports of fifty major urological cases* must be consecutive and must have been under the candidate's own supervision. They must not be abstracted. Sufficient data should appear in these so the examiner will know that a proper history was taken and that a thorough examination, including a complete physical survey, was made.

Case reports that are copied verbatim from a hospital record are not desired. They must be identified by the name of the hospital and the case admission numbers, with the pertinent

dates. The reports must be typewritten (on 8½ by 11 inch paper) and in duplicate, but need not be on any special forms.

The data should be placed under proper headings and the arrangement of these should conform to the sequence of events incidental to the patient's admission to the hospital or clinic, the examinations made and treatment prescribed.

Each candidate must assume personal responsibility for the data in his case reports, including autopsy findings and interpretations of urograms. If the reports are prepared by record clerks, interns, or fellows, they should be reviewed by the candidate and careful attention given to the spelling and the correct use of medical terms before submitting them to the secretary of the board. Case reports are documentary evidence of a candidate's method of practice, and the data in them and the manner in which these are presented reflect this.

Satisfactory case reports must be submitted before a candidate will be permitted to continue with other parts of his examination. If case reports are pronounced unsatisfactory by more than one examiner, the candidate will be informed of this and requested to prepare others. Criticisms and unsatisfactory reports will be sent to the candidate upon request.

Case reports must be submitted to the secretary of the board at least ninety days before the time set for the oral-clinical examination.

Although the board requires that all the essential points of the history and examination be given, as well as a complete description of the surgical procedure, emphasis should be placed

is: preoperative diagnosis; clinical and summary of postoperative course with

special reference to morbidity; clinical findings at time of discharge from the hospital and subsequent "follow-up" reports.

A final short paragraph must be prepared for each case by the candidate. These data must include the candidate's interpretation of the history in terms of pathology; the basis for the diagnosis; the facts that determined the treatment prescribed, whether surgical or otherwise; the course of treatment to be pursued following discharge from the hospital or clinic; a critical discussion of the knowledge gained from the proper handling of the case, or from the errors made (if any) in the diagnosis and method of treatment.

Complete separate index lists of the case history reports submitted must accompany the records. If the reports are obtained from more than one hospital they must be consecutive, as mentioned before, and a separate complete index list of each group of reports should be provided. These lists must state the operator's name at the head of each page, the name of the patient, the hospital and admission number, and the date of operation. The lists will be filed in the secretary's office for verification purposes.

Case reports will be reviewed by examiners living in localities other than those where the candidates practice.

FINAL ACTION

Final action is based on the applicant's training, his professional record, his attainments in the field of urology, and the results of the examinations. Any well trained urologist will have no difficulty in obtaining the board's certification. This board is organized not to prevent qualified urologists from obtaining certificates, but to assist them in becoming recognized in their communities as men competent to practice in the special field of urology.

The activities described above proceed from the certificate of incorporation in which is stated the nature of the business, objects, and purposes proposed to be transacted and carried out by this corporation.

REVOCATION OF CERTIFICATE

Certificates issued by this board are subject to the provisions of the Articles of Incorporation and the By-laws. According to Article IX, Section 4, of the By-laws, "each certificate may be revoked in the event that:

(a) The issuance of such certificate or its receipt by the physician so certified shall have been contrary to, or in violation of, any provision of the Certificate of Incorporation of this, the American Board of Urology, Inc., or of the By-laws; or

(b) The physician or party certified shall not have been eligible to receive such certificate, irrespective of whether or not the facts constituting him so ineligible were known to, or could have been ascertained by, the directors of the board at the time of the issuance of such certificate; or

(c) The physician or party so certified shall have made any misstatement of fact in his application for such certificate or in any other statement or representation to the board or its representatives; or

(d) The physician so certified, at any time while continuing to practice, shall cease to practice urology; or

(e) The physician so certified shall at any time have neglected to maintain the degree of competency in the practice of the specialty of urology as set up by the board, and shall refuse to submit to reexamination by the board.

The Board of Trustees of this Corporation shall have the sole power, jurisdiction and right, to determine and decide whether or not the evidence or information before it is sufficient to constitute one of the grounds for revocation of any certificate issued by this corporation, and the decision of such Board of Trustees in the premises shall be final.*

Communications should be addressed to the secretary-treasurer.

THE AMERICAN BOARD OF PLASTIC SURGERY, INC.

JOHN STAIGE DAVIS, Chairman, Baltimore.

GEORGE M. DORRANCE, Vice Chairman, Philadelphia.

VILRAY P. BLAIR, Secretary-Treasurer, 400 Metropolitan Building, St. Louis.

GUSTAVE AUFRICHT, New York.

JAMES BARRETT BROWN, St. Louis.

ROBERT H. IVY, Philadelphia.

HAROLD L. D. KIRKHAM, Houston, Tex.

WILLIAM S. KISKADDEN, Los Angeles.

SUMNER L. KOCH, Chicago.

WILLIAM E. LADD, Boston.

GORDON B. NEW, Rochester, Minn.

GEORGE WARREN PIERCE, San Francisco.

ERNEST FULTON RISDON, Toronto, Ont., Can.

FERRIS SMITH, Grand Rapids, Mich.

JEROME P. WEBSTER, New York.

HISTORY

The American Board of Plastic Surgery, tentatively organized in June 1937, by representatives of widely distributed groups interested in this special type of surgery, received recognition as a subsidiary of the American Board of Surgery in May 1938, and was given the status of a major board in May 1941 by the Advisory Board for Medical Specialties. It is composed of representatives from the American Association of Oral and Plastic Surgeons, the Surgical Section of the American Medical Association, the American Surgical Association, the Southern Surgical Association and the American College of Surgeons.

The aim of the American Board of Plastic Surgery is to encourage the study, improve the practice, and advance the cause of plastic surgery, and to grant and to issue certificates of recognition of special knowledge in plastic surgery to surgeons meeting the requirements.

PURPOSES OF THE BOARD

The purposes of the board are:

1. To elevate and establish standards of fitness to practice plastic surgery.
2. To arrange and conduct examinations for determining the qualifications of those who request a certificate of their ability in the field of plastic surgery, to establish qualification requirements for applicants, and to confer certificates upon those who meet the requirements of the board.
3. To improve and widen the existing opportunities for the training of the plastic surgeon.
4. To study and evaluate local and foreign teaching centers and opportunities for experience in and the study of plastic surgery.
5. The action or decision of the American Board of Plastic Surgery regarding certification of any candidate shall be final.

GENERAL QUALIFICATION REQUIREMENTS

1. Moral and ethical standing in the profession satisfactory to the board.
2. Membership in the American Medical Association, or, by courtesy, membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association.

PROFESSIONAL QUALIFICATION REQUIREMENTS

1. Graduation from a medical school recognized by the Council on Medical Education and Hospitals of the American Medical Association.
2. Completion of an internship of not less than one year in a hospital approved by the said Council, or what would constitute, in the opinion of the board, the equivalent of such training.

For certification in the field of plastic surgery, the following special training shall be required:

(a) A period of graduate study in surgery of not less than two years beyond the intern year to be taken in a recognized graduate school or hospital.

(b) An additional period of not less than two years of graduate study in plastic surgery, also to be taken in a recognized graduate school or hospital. This period of training shall cover the technical and clinical phases of plastic surgery, and the basic sciences of anatomy, physiology, pathology, bacteriology, and biochemistry as they are related to plastic surgery.

(c) An additional period of two years study and/or practice in plastic surgery.

The above training may be taken in a recognized graduate school of medicine, or as resident in surgery in an acceptable hospital, or under a sponsorship accredited by the American Board of Plastic Surgery for such training. By the latter statement is meant that one may secure the necessary training as an assistant to an accredited surgeon, provided suitable facilities for the education of the candidate are offered. It is understood that the board will accept a combination of such training as outlined above; for example, one may take a graduate course in an acceptable graduate school for one year, a residency for two years, and an assistantship in plastic surgery for two years. Where circumstances permit the applicant to major in plastic surgery during the second of the two years on a general surgical service, the second year of the two years of general training may, with the approval of this board, be credited on his period of special training in plastic surgery.

In exceptional instances, the board may, at its discretion, accept for examination candidates who have met all the above preliminary requirements, have been graduated in medicine at least ten years but whose formal training does not comply with the full requirements to be exacted in the future.

CLASSIFICATION OF APPLICANTS

Until June 1, 1942* applicants for certification shall be classified as follows:

Group A—Founders' Group.—Those to be certified without formal examination as to professional qualifications. This group shall be composed of men who have already amply demonstrated their fitness to do acceptable plastic surgery and who have been graduated in medicine at least ten years.

Group B—Examinees' Group.—Those to be formally examined as to professional qualifications. To be eligible for examination by this board, all candidates shall be required to possess the preliminary and basic medical qualifications accepted by the Advisory Board for Medical Specialties as applied to all specialties.

Applicants who have qualified under Group B shall be required to submit twenty-five diversified case reports, together with photographs of before and after treatment made from unretouched negatives.

EXAMINATIONS

The qualifying examination will be divided into Part I, written, and Part II, oral and practical.

Part I shall consist of a written examination upon questions prepared by the examining committee which concern the theory and practice of plastic surgery. In addition to the above, the examination shall include questions upon applied anatomy, applied physiology, pathology, clinical laboratory methods, local and general anesthesia, shock, hemorrhage, the handling of tissues, wound healing, related bacteriology, and surgical accidents, all as related to plastic surgery.

Part II shall, as far as possible, be of a practical nature, and shall be conducted by no fewer than two competent judges, selected by the examining committee.

The clinical examination shall include any or all of the following:

(a) The exhibition of patients who have undergone or who are undergoing treatment.

(b) Examination, diagnosis, and presentation of a plan of correction by the applicant of cases provided by the examiners.

(c) Oral examination of the applicant and observations made in the operating room, treatment rooms, and wards.

In order to be eligible for Part II of the examination, a candidate shall have successfully passed Part I.

A candidate shall be required to receive a passing average for each Part in order to receive the board's certificate. No candidate shall pass Part I or Part II of the examination who does not receive a grade of 65 per cent or over in each subject of each Part. An average grade of 75 per cent shall be considered as passing.

* At the discretion of the board this closing date for the Founders' Group may be extended until June 1, 1943.

REEXAMINATIONS

Candidates may be reexamined as often as they desire, provided that one year shall elapse between examinations, except in such case as the board may, for good and sufficient reason, deny a candidate the privilege of reexamination.

FEES

The fee for the examination and the certificate of the American Board of Plastic Surgery is \$100. Of this sum \$25, which is not returnable, must accompany the case reports; \$25 should be paid when Part I of the examination is taken, and \$50 when Part II is taken. There shall be no refunds.

This fee may be increased at the discretion of the board, when the number of candidates decreases and when the expenses of the examinations and other activities of the board demand.

This board is a nonprofit organization. The fees of candidates are used solely for defraying the actual expenses of the board. The members of the board and their associates receive no emoluments. All surplus moneys derived from fees will be used to aid in improving existing opportunities for the training of plastic surgery.

The fee for the Founders' Group is \$50.

CERTIFICATION

A certificate, bearing the seal of the board and the signatures of its officers, will be issued to each successful candidate attesting his qualification in plastic surgery.

REVOCATION OF CERTIFICATE

The American Board of Plastic Surgery shall have the sole power, jurisdiction, and right to determine and decide whether or not the evidence or information placed before it is sufficient to constitute grounds for revocation of any certificate issued by the board, and the decision of the board in the premises shall be final.

AMERICAN BOARD OF NEUROLOGICAL SURGERY, INC.

HOWARD C. NAFFZIGER, Chairman, San Francisco.
ALFRED W. ADSON, Vice-Chairman, Rochester, Minn.
R. GLEN SPURLING, Secretary-Treasurer, 404 Brown Building, Louisville, Ky.
PAUL C. BUCY, Chicago.
WINCHELL MCK. CRAIG, Rochester, Minn.
LEO M. DAVINOFF, Brooklyn.
LOYAL DAVIS, Chicago.
TEMPLE S. FAY, Philadelphia.
MAX M. PEET, Ann Arbor, Mich.
TRACY J. PUTNAM, New York.
ERNEST SACHS, St. Louis.
BYRON STOOKEY, New York.

ORGANIZATION

Recognizing the need for detailed training and special qualifications for the practice of neurological surgery, representatives of both the Society of Neurological Surgeons and the Harvey Cushing Society held an informal meeting in Chicago on March 27, 1939, to consider the advisability of the formation of a national certification board. Later the group was enlarged by representatives from the Section on Nervous and Mental Diseases of the American Medical Association, the Section on Surgery of the American Medical Association, the American Neurological Association, and the American College of Surgeons. Approval of the board by the Advisory Board for Medical Specialties and the Council on Medical Education and Hospitals of the American Medical Association was given. The American Board of Neurological Surgery was incorporated in the State of Delaware on Aug. 1, 1940.

The membership of the corporation was nominated as follows: five from the Society of Neurological Surgeons, three from the Harvey Cushing Society, one each from the American College of Surgeons, the Section on Nervous and Mental Disease of the American Medical Association, the Section on Surgery of the American Medical Association, and the American Neurological Association.

PURPOSES

A. To encourage the study, improve the practice, elevate the standards and advance the science of neurological surgery and thereby to serve the cause of public health.

B. To grant and issue to physicians duly licensed by law, certificates or other recognition of special knowledge in neurological surgery and to suspend and revoke the same.

C. Certificates granted or issued by the corporation shall not confer or purport to confer on any person any legal qualifi-

cation, privilege or license to practice neurological surgery, nor purport to be issued under or in pursuance to or by virtue of any statutory or governmental sanction or authority.

D. To determine by examination, investigation and otherwise the fitness and competence of specialists in neurological surgery who shall apply for certificates and to prepare, provide, control and conduct examinations, written, oral and otherwise, for such purpose and to determine the results of such examination.

E. To furnish to the public, hospitals, medical schools, medical societies and practitioners of medicine and surgery lists of neurological surgeons who from time to time have been granted certificates by this corporation.

GENERAL REQUIREMENTS

A. General qualifications.

1. Satisfactory moral and ethical standing in the profession.

2. License to practice medicine.

3. Membership in the American Medical Association or, by courtesy, membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association.

4. That the surgical activity of the applicant shall be limited to neurological surgery.

B. Professional education.

1. Graduation from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association, or graduation from a foreign school which is acceptable to the American Board of Neurological Surgery, Inc.

C. Special training, to be effective Jan. 1, 1940.

1. Completion of a surgical internship of not less than one year in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association, or its equivalent in the opinion of the board.

2. A period of graduate study in a recognized graduate school of medicine of not less than three years beyond the intern year, or in an approved hospital or under a sponsorship acceptable to the American Board of Neurological Surgery, Inc., for the training of neurological surgeons. This period of special training shall be of such a character that the relation of the basic sciences of anatomy, physiology, pathology, bacteriology and biochemistry is emphasized. Knowledge of these sciences as applied to the practice of neurological surgery will be required in the examination.

3. An additional period of not less than two years in the practice of neurological surgery.

D. Certification without examination.

1. On invitation by the board and written application made within two years from Jan. 1, 1940, the following may be accepted as eligible for certification upon approval of the board of directors and on the production of evidence of satisfactory moral and ethical standing in the profession.

(a) Individuals of professorial rank in approved medical schools of the United States or Canada whose surgical practice is limited to neurological surgery.

(b) Those who have specialized in neurological surgery for ten years prior to Jan. 1, 1940.

APPLICATION BLANK AND FEE

Application must be made on the special form which may be procured from the secretary. The application and examination fee for candidates is \$75 whether certified with or without examination. The completed application form should be returned to the secretary accompanied by an application fee of \$25. When notified by the secretary that he is eligible for examination he shall send the examination fee of \$50 to the secretary-treasurer at least two weeks before the date of examination. The application fee will be returned if the candidate is not accepted by the board for examination.

A candidate who has failed in one examination is eligible to reexamination in the subject, or subjects, in which he failed, within three years, on payment of a reexamination fee of \$10. A candidate who has failed in one examination and who does not apply for reexamination within three years or a person who has applied within that time but who has failed a second time will be considered a new applicant.

EXAMINATIONS

Examinations will be held in the spring and fall of each year at or near the time and place of a national meeting at the discretion of the board. Examinations will be oral and based upon broad principles of neurological surgery. The subject matter of the examination will be divided into six parts: (1) neuroanatomy and neurophysiology, (2) neuropathology and

bacteriology, (3) ophthalmology and x-ray diagnosis, (4) neuro-surgical problems, (5) organic neurology and (6) general surgery.

All communications should be addressed to the secretary-treasurer.

ADVISORY BOARD FOR MEDICAL SPECIALTIES

Organized 1933-1934 to coordinate graduate education and certification of medical specialists in the United States and Canada.

This Board reports directly to its member groups, and functions in close cooperation with the Council on Medical Education and Hospitals of the American Medical Association and with the Advisory Council on Medical Education.

The work of this Board has been aided by grants from the Josiah Macy Jr. Foundation of New York, but the Board is now supported by its component groups.

OFFICERS AND EXECUTIVE COMMITTEE

WILLARD C. RAPPLEYE, President, New York.
WILLIAM P. WHERRY, Vice President, Omaha.
C. GUY LANE, Secretary-Treasurer, 416 Marlboro Street, Boston.
R. C. BUECKI, Philadelphia.
WALTER B. LANCASTER, Hanover, N. H.

FOREWORD

The Advisory Board for Medical Specialties has prepared these data for the purpose of furnishing general information regarding its activities in connection with graduate medical education and the certification of medical specialists in the United States and Canada. It is designed also to give detailed information concerning the procedure to be followed by examining boards in the various specialties in order to obtain membership in this Advisory Board and official recognition by the Council on Medical Education and Hospitals of the American Medical Association. This information is based in large part on the experience of previously formed boards during the past twenty-five years.

ORGANIZATION

This Advisory Board was organized in 1933-1934 to coordinate graduate education and certification of medical specialties in the United States and Canada.

Several specialty boards had been functioning actively and successfully for a number of years prior to the organization of the Advisory Board for Medical Specialties. Their purposes were, primarily, to establish minimum standards of graduate educational and training requirements for physicians representing themselves to the public as being specialists, with certification by the boards of candidates after they had been able successfully to pass the boards' examinations. Secondly, these boards hoped to improve the general standards of graduate medical education and facilities for special training. This aim is being steadily and rapidly accomplished.

Credit for the improvement in undergraduate medical education, so noticeable in this country during the past twenty-five years, is due to the efforts of universities, educational foundations, medical schools, medical societies, and to public support along these lines. The same is true of the present transition in graduate education in the specialties, sharply stimulated by the establishment and activities of these certifying boards.

The American Board of Ophthalmology was the first special certifying board to be created in 1916; the American Board of Otolaryngology, established in 1924, was followed by the American Board of Obstetrics and Gynecology in 1930, and the American Board of Dermatology and Syphilology in 1932.

During part of this period of time plans for the organization of similar boards in other specialties were being actively projected, all of these groups being desirous of availing themselves of the experiences of the already existing boards.

It was soon recognized that some formal and official plan of organization must be established. It was clearly essential that an examining board must have the official sanction of the national societies in its given specialty as well as that of its section of the American Medical Association, but there was, at that time, nothing to prevent unofficial groups from organizing examining boards and using the title American Board.

Consequently, in order to avoid duplication of effort as well as to coordinate the work of the several boards and other interested groups into a concise and homogeneous plan for betterment, it was deemed advisable to create an Advisory Board which should give consideration to those problems common to all, and which should be representative of each organization concerned.

During the years 1933 and 1934 this Advisory Board was organized and began actively to function. Simultaneously at the Milwaukee session of the American Medical Association in 1933 a resolution was adopted authorizing the Council on Medical Education and Hospitals: (1) to formulate standards of administration based in general upon those of the American Boards of Ophthalmology, of Otolaryngology, of Obstetrics and Gynecology, and of Dermatology and Syphilology and, (2) to recognize officially new boards meeting these standards, this recognition to be based upon previous approval and recommendation to the Council by the Advisory Board.

A constitution and by-laws for the Advisory Board was adopted at a meeting in Chicago on February 11, 1934. The original member organizations of the Advisory Board for Medical Specialties were: the Association of American Medical Colleges; the American Hospital Association; the Federation of State Medical Boards of the U. S. A.; the National Board of Medical Examiners; the American Board of Ophthalmology, founded 1916; the American Board of Otolaryngology, founded 1924; the American Board of Obstetrics and Gynecology, founded 1930; and the American Board of Dermatology and Syphilology, founded 1932. Two representatives were appointed from each of these organizations to serve on the Advisory Board. Since that time the American Boards of Pediatrics (1934), of Psychiatry and Neurology (1934), of Radiology (1934), of Orthopaedic Surgery (1935), of Urology (1935), of Pathology (1936),

of Internal Medicine (1936), of Surgery (1937), of Anesthesiology (1938), of Plastic Surgery (1938), and of Neurological Surgery (1940) have been properly organized, approved, and elected to membership in the Advisory Board and recommended to the Council on Medical Education and Hospitals of the American Medical Association for official recognition. There are, therefore, fifteen examining boards now organized, approved and actively functioning in the fifteen specialties recognized as suitable fields for the certification of specialists.

The work of this board has been aided by grants from the Josiah Macy, Jr., Foundation of New York, but the board is now supported by its component groups.

PURPOSE

Article II of the Constitution states that, "This board shall act in an advisory capacity to such organizations as may seek its advice concerning the coordination of the education and certification of medical specialists." Specifically, this represents an official effort to advance the standards and improve the methods of graduate education and training in the medical specialties, with certification of men thus educated and trained who qualify as specialists in the various branches. The common interest of the member organizations in these purposes is obvious. It is equally apparent that some fixed definition of specialties needed to be established, preferably on a graduate educational basis, that minimum standards of organization and conduct for new examining boards should be fixed, and that some official method of recognition be developed.

There is no desire on the part of these boards to interfere with any practitioners of medicine in any of their regular or legitimate activities. Their fundamental purpose is to ensure to the public, both lay and medical, and for its protection, that physicians claiming to be specialists with presumably special proficiency in one or another branch of medicine actually possess the qualifications they claim. This presupposes special training and demonstrable capability along certain lines of work. Suitable evidence of this is the ability of an individual to satisfy an examining board about his training and then to pass the examination for certification.

Surveys of existing facilities for graduate training in the various specialties are being conducted at the present time; residencies as well as preceptorship and assistantship training are being studied; preparations for stimulating medical school and hospital facilities for the required graduate training are going forward actively; round table conferences furnish discussions of subjects of interest in regard to graduate medical education.

The Council on Medical Education and Hospitals of the American Medical Association has agreed, under the authority vested in it by the resolution passed at the Milwaukee meeting (1933) and referred to above, that applications of special examining boards for official approval are to be referred to the Council through the Advisory Board for Medical Specialties, recommendation by the Advisory Board for such approval to be based upon the standards mutually adopted. The understanding exists that the Council cannot be bound by recommendations of the Advisory Board but will consult the Advisory Board for Medical Specialties before acting upon any application so long as mutually adopted standards are in force.

Early in 1940 there was published the first edition of the Directory of Medical Specialists containing the names and biographic data of all men certified by the several specialty boards, as well as information regarding the organization and functions of these boards. In the next edition to be published early in 1942 will appear the names and brief biographic records, including hospital and teaching appointments, of about 18,000 diplomates or certified specialists.

In response to the generally recognized need for a clear formulation of the educational problems and principles involved in graduate and postgraduate medical training, the Advisory Board at its meeting in June 1937 voted to create a Commission on Graduate Medical Education to study the various aspects of the whole problem. This commission included representatives of the profession, the specialties, the universities, the hospitals, and the licensing bodies. The report of this commission comprising 304 pages appeared in 1940, published by the University of Chicago Press, and is of real assistance to the various specialty boards, hospitals, medical schools, and regulatory bodies dealing with this phase of American medicine.

MEMBERSHIP

The Advisory Board is composed of two representatives from each of the approved examining boards in the medical specialties and such other national organizations as are interested in education, examination, and certification of medical specialists and duly elected to this body.

The Constitution provides that, "To be eligible for representation in this board an examining board in a specialty must be composed of members elected from or appointed by societies recognized by this board as a national society in that specialty together with representation from the related section of the American Medical Association." Upon being accepted by the Advisory Board the board in question is recommended to the Council on Medical Education and Hospitals of the American Medical Association as qualified for recognition. Membership in the Advisory Board provides for the inclusion of the name of the organization in all lists and directories published by the Advisory Board for Medical Specialties and provides also for publication of the names of specialists certified by each individual examining board.

This board reports directly to its member groups, and functions in close cooperation with the Council on Medical Education and Hospitals of the American Medical Association, and with the Advisory Council on Medical Education.

The Advisory Board has voted that no more subsidiary boards be formed and that further special groups be provided for, so far as possible, with the boards of medicine and surgery.

Meetings of the Advisory Board for Medical Specialties are held annually as required.

Traveling and other expenses of representatives in attendance are borne by member organizations.

ESSENTIALS FOR APPROVED SPECIAL EXAMINING BOARDS

I. ORGANIZATION

1. A special examining board to be approved by the Advisory Board for Medical Specialties should represent a recognized and distinct specialty of medicine. (It is agreed between the Council and the Advisory Board that no board shall be organized in a special field having less than one hundred members engaged in special practice in the United States.)

2. It should be composed of representatives of the national organizations in that specialty including the related section of the American Medical Association.

3. It should be incorporated.

4. A special board should:

(a) Determine whether candidates have received adequate preparation.

(b) Provide a comprehensive test of the ability and fitness of such candidates.

(c) Certify to the competence of those physicians who have satisfied its requirements.

II. DEFINITION OF SPECIAL FIELDS

The following branches of medicine at present are recognized as suitable fields for the certification of specialists:

1. Internal Medicine
2. Surgery
3. Pediatrics
4. Obstetrics and Gynecology
5. Ophthalmology
6. Otolaryngology
7. Dermatology and Syphilology
8. Psychiatry and Neurology
9. Urology
10. Orthopaedic Surgery
11. Radiology
12. Pathology
13. Neurological Surgery
14. Anesthesiology
15. Plastic Surgery

III. QUALIFICATION OF CANDIDATES

Each applicant for admission to the examination should be required to present evidence that he has met the following standards:

A. General Qualifications.

1. Satisfactory moral and ethical standing in the profession.

2. Membership in the American Medical Association or membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association is recommended. Membership in other societies should not be required. (Exceptions to the foregoing may now be made at the discretion of any individual board for good and sufficient reasons.)

B. Professional Standing.

1. Graduation from a medical school recognized by the Council on Medical Education and Hospitals of the American Medical Association.

2. Completion of an internship, preferably of the general rotating type, of not less than one year in a hospital approved by the same Council.

C. Special Training.

(To be effective as far as practical not later than Jan. 1, 1944.)

1. A period of study, after the internship, of not less than three years in clinics, dispensaries, hospitals or laboratories recognized by the same Council as competent to provide a satisfactory training in the special field of study.

2. This period of specialized preparation should include:

(a) Graduate training in anatomy, physiology, pathology, and the other basic medical sciences which are necessary to the proper understanding of the specialty in question.

(b) An active experience of not less than eighteen months in hospital clinics, dispensaries and diagnostic laboratories recognized by the Council as competent in the specialty.

(c) Examinations in the basic medical sciences of a specialty as well as in the clinical, laboratory and public health aspects.

3. An additional period of not less than two years of study and/or practice.

These essentials were adopted by the Advisory Board for Medical Specialties June 10, 1934 and have had only minor changes since then. They are practically identical with an outline of Essentials for Approved Specialty Boards adopted June 10, 1934 by the Council on Medical Education and Hospitals of the American Medical Association and ratified June 11, 1934 by the House of Delegates of the American Medical Association.

ORGANIZATION OF EXAMINING BOARDS

The foregoing essentials for approved special examining boards were followed in the organization of the existing boards.

Official sponsorship of the national societies, and the related section of the American Medical Association, in a specialty organizing an examining board, has included the election or appointment of representatives from each of these national societies to serve on the board as examiners and directors.

Each board was or is incorporated. Each application for organization and approval included:

1. The name of the proposed board.
2. A statement of its method of organization, the sponsoring societies, its list of officers, and the names and addresses of the elected or appointed members of the board, including the societies which each represents.
3. A copy of the tentative constitution and by-laws.
4. A copy of its proposed articles of incorporation.
5. An outline of qualification requirements for applicants.
6. An outline of proposed methods of examination.
7. A copy of the application blank.
8. Any general information or statement of importance.
9. Approximate number of physicians practicing the specialty which the board represents.

These data are submitted in duplicate to the office of the Secretary of the Advisory Board for Medical Specialties. An application for election to membership in the Advisory Board and the data listed above are referred immediately for review by the Committee on Standards and Examinations of the Advisory Board. Upon approval by the committee incorporation is then completed and a statement of this filed with the secretary. Action on the application will be taken at the succeeding meeting of the Advisory Board for Medical Specialties and each examining board as elected will be recommended to the Council on Medical Education and Hospitals of the American Medical Association for official recognition. One of the two sets of data submitted is forwarded to the Council on Medical Education and Hospitals of the American Medical Association with the Advisory Board's recommendations. Examination and certification of applicants in the specialty may begin immediately when the special board is given such approval. Communications should be addressed to the secretary.

CONSTITUTION AND BY-LAWS

Adopted at Organization Meeting, February 11, 1934

ARTICLE I

NAME

The name of this organization shall be "The Advisory Board for Medical Specialties."

ARTICLE II

PURPOSE

This board shall act in an advisory capacity to such organizations as may seek its advice concerning the coordination of the education and certification of medical specialists. No action taken by this Board shall be binding upon any member organizations.

ARTICLE III

MEMBERSHIP

Section 1

This board shall be composed of two representatives from each of the examining boards of the medical specialties and such other national organizations as are interested in education, examination, or certification of medical specialists.

Section II—Original Membership

At the time of the organization, this board shall be composed of representatives from each of the following bodies:

- The American Board of Ophthalmology.
- The American Board of Otolaryngology
- The American Board of Obstetrics and Gynecology
- The American Board of Dermatology and Syphilology
- The Association of American Medical Colleges
- The National Board of Medical Examiners
- The Federation of State Medical Boards of the U. S. A.
- The American Hospital Association
- The Council on Medical Education and Hospitals of the American Medical Association

Section III—Additional Membership

To be eligible for representation in this board an examining board in a specialty must be composed of members elected from or appointed by societies recognized by this board as national societies in that specialty together with representation from the related Section of the American Medical Association. Upon being accepted by this Advisory Board the board in question will be recommended to the American Medical Association as being qualified for recognition by that Association.

Section IV—Quorum

A quorum at any meeting shall consist of a majority of the official representatives to the board and at least one-third of the membership organizations shall be represented. Each member organization shall be entitled to two votes.

ARTICLE IV

OFFICERS AND STANDING COMMITTEES

Section I—Officers

The officers of this board shall be (a) President, (b) Vice President, (c) Secretary-Treasurer. These officers shall be elected at the annual meeting each year.

Section II—Standing Committees

The standing committees shall be as follows:

1. The Executive Committee
2. Standards and Examinations
3. Finance

The Executive Committee shall consist of the President, Vice President, Secretary-Treasurer, and two members elected at the annual meetings. No organization should have more than one member on the Executive Committee. The President shall be the Chairman of the Executive Committee. The other standing committees shall be appointed by the President.

ARTICLE V

AMENDMENTS TO THE CONSTITUTION

Amendments to this constitution may be made by a majority vote of the official representatives present at any annual meeting provided that thirty days' notice of the proposed amendment has been given each member of the board.

BY-LAWS

ARTICLE I

DUTIES OF OFFICERS

Section I

The President shall preside at all meetings of the board, shall act as Chairman of the Executive Committee, and shall appoint all other standing committees. He shall call meetings of the Executive Committee at such time and place as may be deemed necessary.

Section II

The Vice President shall assume the duties of the President in his absence.

Section III

The Secretary-Treasurer shall perform the usual duties of this office.

ARTICLE II

EXECUTIVE COMMITTEE

The Executive Committee shall carry out the policies and activities decided upon by the board. It shall have an interim authority to initiate policies subject to approval by the board at the annual or any special meeting. The two elected members shall serve for two years, the terms of office terminating in alternate years.

ARTICLE III

MEETINGS

Section I

There shall be an annual meeting at such time and place as the board may determine. A special meeting may be called by the president upon ten days' notice to all members stating time, place and purpose of such meetings. The Executive Committee may present other business for consideration.

Section II

The Executive Committee shall meet subject to the call of the President.

Section III

Robert's Rules of Order shall be followed except where they conflict with this Constitution and By-Laws.

ARTICLE IV

AMENDMENTS TO THE BY-LAWS

Amendments to these by-laws may be made at any regular or special meeting of the board.

HOSPITALS APPROVED FOR TRAINING INTERNS

By the Council on Medical Education and Hospitals of the American Medical Association

The following general hospitals are considered in position to furnish acceptable internships of at least one year duration. They are also accredited for mixed residencies, which represent general assignments following an approved intern service.

The + sign indicates additional approval for residencies in specialties.

HOSPITALS, 735. INTERNSHIPS, 6,874

Capacity, 249,045 Beds

The terms used in the column "Type of Internship" are defined as follows:

1. A full rotating internship provides training in medicine, surgery, pediatrics, obstetrics, pathology and radiology. (X-ray and laboratory duties may be combined with clinical services or constitute separate assignments.)

2. A mixed or limited rotating internship covers more than one of the clinical specialties but does not include all of the divisions listed above.

3. A straight internship is an assignment limited to a single department but may include the subspecialties of the same branch. Straight internships are now approved in the divisions of medicine, surgery, pediatrics, pathology, obstetrics and obstetrics-gynecology.

HOSPITALS APPROVED FOR INTERNSHIPS IN THE DOMINION OF CANADA

For the benefit of graduates of approved medical colleges who desire an internship in Canada, the Council on Medical Education and Hospitals of the American Medical Association has declared that hospitals which conform to the standards of the Department of Hospital Service of the Canadian Medical Association should be regarded as giving an internship equivalent in educational value to that offered by hospitals in the United States approved for intern training by the Council. It is understood, however, that this statement applies only to hospitals that are unqualifiedly "Approved" under the Canadian plan and does not apply to that group referred to as "Commended."

The following list of hospitals, revised to June 1, 1941, has been furnished by the Department of Hospital Service.

Name of Hospital	Location	Name of Hospital	Location	Name of Hospital	Location
Victoria General Hospital	Vancouver, B. C.	McKellar General Hospital	Hamilton, Ont.		
		St. Joseph's Hospital	Ottawa, Ont.		
		Ottawa Civic Hospital	Ottawa, Ont.

APPROVED RESIDENCIES AND FELLOWSHIPS

Council on Medical Education and Hospitals of the American Medical Association,
535 North Dearborn Street, Chicago

Hospitals, 616; Residencies, 4,683; Fellowships, 550

The following institutions approved by the Council on Medical Education and Hospitals are considered in position to furnish acceptable training in various specialties as indicated below. Residencies in specialties, as defined by the Council, are straight services of one or more years following an approved internship. A fellowship is a form of apprenticeship which in some cases is indistinguishable from a residency, although it usually offers greater opportunity for the study of basic sciences and research. Ordinarily a fellowship is a university rather than a hospital appointment. Mixed residencies are general hospital assignments following internship. They include services classified as general residencies and chief residencies.

The star (*) indicates hospitals that are also approved for the training of interns. All hospitals on the approved intern list are likewise accredited for general or mixed residencies.
